

otherwise using it. The bulk of the ragweed growing on vacant lots, along highways and in alleyways, however, must be controlled on a city-wide basis.

Highway and public works departments with a practical knowledge of the factors which promote the growth of ragweed plants, can do much to prevent their growth in the development and maintenance of streets and highways. There is a striking difference between the amount of ragweed growing along the depressed speedways in New York City and that growing along service roads feeding these highways, particularly in the suburban areas of the city. Plant cover is required to control erosion along the banks of the depressed highways and this cover, which is usually grass, Japanese honeysuckle or barberry bushes, provides the competition which prevents the growth of ragweed.

Due to a marked increase in city-wide budget costs during this post-war period, it was not possible to purchase new equipment. Therefore, all available community resources were utilized in the ragweed control program. The Commissioner of Health secured the whole-hearted support of the Mayor who personally requested the coöperation of a number of city departments which were most helpful in the development of a practical control program.

The Health Department was the coordinating agency having responsibility for planning the budget and providing technical and supervisory guidance. It also carried on education and public relations on a city-wide basis. Several ragweed sufferers' groups assisted in this part of the program.

The Borough Presidents' Offices, that have jurisdiction over the streets in New York City assumed responsibility for the spraying. They engaged the labor, routed the trucks and supervised the men doing the work. They also released the information regarding the

progress of the program in each borough.

The Department of Sanitation loaned the street flushers which were converted to provide power units for the spraying operations. The Department of Health and the Borough Presidents' Offices co-operated in properly equipping the trucks with hose connections, spraying nozzles and the like. The Park Department sprayed ragweed growing on the property under its jurisdiction. The Police Department, through its precinct safety inspectors, mapped the city showing the location and extent of all of the ragweed growing within its limits.

It is recognized that the control of ragweed is for the purpose of reducing pollen and, thereby, hay fever symptoms and should not be thought of in terms of a few square miles. The area of the City of New York covers over 320 square miles, but maximum benefits will require supporting programs in the adjacent communities. Considerable work has been done by the department to promote an interest in ragweed control programs throughout the metropolitan area of New York. This area includes sections of the States of New York, Connecticut, and New Jersey, and the area within a 50 mile radius of central Manhattan.

New York University, in coöperation with the Department of Health, conducted a course in the "Control of Plants Detrimental to Health." Two hour sessions were held on 6 Friday evenings during the spring of 1947. Over 100 people from the metropolitan area and even beyond took the course. A number of communities in this area initiated ragweed control programs, and it is anticipated that the number will increase from year to year as the success of these programs is demonstrated.

The Brooklyn Botanic Garden and the City Health Department sponsored a joint conference on the "Control of Plants Harmful and Annoying to Man."

TABLE 3

| Salary Range | Supervisory and Consultant | Staff Level | Graduate Registered |
|-------------------|-------------------------------|-----------------|---------------------|
| Total Reported | 534 | 1,530 | 647 |
| Median | \$3,100-\$3,200 | \$2,300-\$2,400 | \$2,000-\$2,100 |
| Highest | \$5,500-\$5,600 | \$3,500-\$3,600 | \$3,200-\$3,300 |
| Lowest | Under \$2,400 | Under \$1,800 | Under \$1,600 |
| Number Receiving | | | |
| More than \$3,000 | 363 | 64 | 2 |
| Less than \$2,400 | 3 | 842 | 597 |

mode, affecting 142 persons, between \$2,400 and \$2,600. Only 6 per cent received \$5,000 or more and nearly one-fourth less than \$2,400. As to regional medians, the median for Eastern and for North and South West Central states was equal to that of the country as a whole, that for the 12 Southern states lower, and for other areas higher.

Public health nursing personnel was divided into four categories—directors of public health nursing, supervisory and consultant nurses, staff level nurses, and graduate registered nurses. The three latter groups were found in the ratio of one, three, and one and one-fifth.

All but 2 of the 48 states reported salaries for directors of public health nursing. These salaries ranged from \$3,200 to \$7,375 with \$4,200 as the median. In 7 states only was the salary \$5,000 or over; in 8 states it was \$3,600 or less.

The median salary for the supervisory and consultant group was between \$3,100 and \$3,200. For the 534 reported positions salaries range from less than \$2,400 to \$5,600. However only 5 persons received \$4,800 or over, and only 33 received \$4,000 or more, while about one-third received less than \$3,000.

The ranges of salaries for the three groups of nurses in the field of public health other than directors are shown in Table 3.

State directors of dental health serv-

ices were reported for 44 states. The highest salary paid was \$7,100 in one state, a state in which the director of maternal and child health, of venereal disease control, of tuberculosis control, and of sanitary engineering were paid respectively \$7,680, \$7,080, \$8,280, and \$8,280. The median salary for dental health directors was \$5,400. Fourteen salaries were below \$5,000 and 8 were above \$6,000.

State directors of vital statistics were reported for 47 states. The salary range for this group of workers was from \$2,400 to \$8,000 while the median was \$4,500. In only 3 states was this position paid at \$6,000 or more and in 15, less than \$4,000.

Nutritionists. Salary reports were received for approximately 100 nutritionists on the staffs of state health departments. For these the median salary was \$3,000-\$3,100, affecting 14 persons. Only 6 persons received more than \$4,000 and 18 received less than \$2,700. Nearly half of the total number received between \$2,700 and \$3,200. Because of the small numbers involved this group was not classified either by state or by region.

It is now expected that similar studies will be made annually. It is hoped that the experience of this first study can be used to refine job definitions and classifications so that comparisons will be meaningful in terms of training and responsibility.

Greater Dishwashing Sanitation Is Assured by the **Salvajor**

**...the Scrapping and
Pre-Washing Machine
that ...**

...Decreases Bacteria Count

Salvajor pre-washed tableware goes into the dishwashing machine nearly clean. This lowers the bacteria count within the dishwashing machine, and the washed dishes and silverware are consequently more sanitary.

...Keeps Dishwashing Machine Wash Water Cleaner

The dishwashing machine does a better job, because scrapping and pre-washing in the Salvajor's gusher of warm water reduces the refuse in the dishwashing machine wash water. Water used by the Salvajor is maintained at a temperature which removes grease yet does not bake dairy products on dish surfaces.

...Improves Dish Pantry Sanitation

Scrapping with the Salvajor eliminates messy scrapping blocks, open garbage cans. Garbage collected in the Salvajor scrap basket is cleaner; rancid, odor-forming liquids are washed away.

Many food serving establishments use the Salvajor to protect public health. The Salvajor is acknowledged by many sanitarians to be the outstanding advancement toward greater dishwashing efficiency in recent years.

APPROVED BY HEALTH DEPARTMENTS

The Salvajor is not a garbage disintegrator. It reduces garbage volume by removing liquid content. The machine has an auxiliary over-flow which prevents back-siphonage.

Health departments in New York City, Los Angeles, Chicago and other metropolitan areas have approved the Salvajor. The Salvajor has been designed to comply with health and sanitation regulations throughout the country.

DR. CARL BUCK JOINS UNIVERSITY OF MICHIGAN FACULTY

Carl E. Buck, Dr.P.H., was appointed to the staff of the Committee on Administrative Practice, American Public Health Association, March 31, 1931. During most of the intervening years he has served as Field Director for the Association and the committee. He has now resigned from this position to become Resident Lecturer in Public Health Practice at the University of Michigan School of Public Health, Ann Arbor. His special interest will continue in the field of state and local health administration.

Dr. Buck's host of friends throughout the North American Continent will be glad to know that his unusual talents and his wealth of practical experience have been transferred to a point where his influence may be extended through his students to influence public health practice in the future. He has acquired the kind of information and experience possessed by almost no other person during the last 17 years. His mark has been made on the Committee on Ad-

ministrative Practice, on the Association, and upon local and state health services in North America.

Besides many studies and reports which Dr. Buck has made on local health agencies, both official and voluntary, there should be recorded the unprecedented series of state studies conducted by Dr. Buck during the last 11 years. Beginning with a study of Ohio in 1931, Dr. Buck's interests were extended through studies in Arizona in 1936; Massachusetts, 1936; Oklahoma, 1938; Michigan, 1939; Florida, 1939; Alaska, 1940; Louisiana, 1941; Manitoba, 1941; Illinois, 1942; Washington, 1942; Alaska (re-study), 1943; California, 1943; Oregon, 1944; Utah, 1944; Idaho, 1945; Colorado, 1946; Wyoming, 1946; Montana, 1946; North Dakota, 1947. After completing a second study of Massachusetts during the fall of 1947, Dr. Buck finished his term of service with the Association by a re-study of the California State Department of Health. Dr. Buck has announced that he will continue an interest in field work in a consulting capacity.

1. FAST

Dermesthetic Ointment contains benzyl alcohol, which works fast but doesn't last. So the second agent takes over . . .

2. OVERLAPPING

Phenol offers intermediate relief —with moderately prolonged effect. And it in turn is overlapped by the third agent . . .

3. PROLONGED

Benzocaine, which has already begun to soothe the affected areas, continues to relieve itching over a prolonged period.

NEW TRIPLE-ACTION

RELIEF!

CUTTER DERMESTHETIC OINTMENT* gives 3-phase control of pruritus! Acts fast—medium—slow! It relieves itching at once! It prolongs the soothing effect! It minimizes psychic trauma.

And here's the reason why...Cutter Dermesthetic Ointment provides three anesthetic properties with overlapping action.

Fast-acting, long-lasting Dermesthetic Ointment stops itching caused by poison ivy, poison oak, insect bites, industrial rashes and other pruritic conditions. Greaseless, it does not dissolve and spread oil-soluble irritants. It can be removed easily, will not stain skin or clothes.

While not intended as a bactericidal agent, Dermesthetic Ointment with its benzyl alcohol and phenol content is bacteriostatic. This bacteriostatic action, in combination with the quick, lasting relief from pruritus, helps to avoid possible infection from scratching.

Try it, won't you? Clinical samples will be sent on request.

*Cutter's trade name for Anesthetic Ointment

CUTTER

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

(Supplemental to list in April Journal)

POSITIONS AVAILABLE

Epidemiologist for responsible state-wide program in communicable disease control requiring an experienced health officer.

Senior Bacteriologist for responsible positions in state public health Laboratories. Master's degree or experience necessary. Monthly salary \$250-\$315.

Junior Bacteriologist for positions available in state public health laboratories. Bachelor's degree with major in bacteriology or immunology required. Monthly salary \$210-265. Contact Personnel Office, Kansas State Board of Health, Topeka, Kans.

Employment Opportunities in Arizona Wanted—Medical and Other Professional Personnel in Arizona

Director of Tuberculosis Control Division, \$6,000 a year

Director of Maternal and Child Health Division, \$6,000 a year

Two Directors of Local Health Units, \$5,100 a year

Maternal and Child Health Clinician, \$5,100 a year

Clinician in the Special Field of Cancer, \$5,100 a year

Director, Hospital Survey, Planning and Construction, \$6,000 a year

Nutrition Consultant, \$3,360 a year

Dental Hygienist, \$2,400 a year

Assistant Director of Health Education, \$2,880 a year

Psychiatric Social Work Consultant, \$3,360 a year

Consulting Psychologist, \$3,360 a year

Senior Psychologist, \$2,880 a year

Junior Psychologist, 2,400 a year

Personnel Officer, \$3,000 a year

Vital Statistician, \$2,880 a year

Public health program operates under a Merit System of Personnel Administration. For further information write to: J. P. Ward, M.D., Superintendent of Public Health, Phoenix, Ariz.

Public Health Nurse wanted with Public Health Certificate. Beginning salary \$3,051 to maximum of \$3,577. Car furnished. Permanent tenure, vacation and sick leave, 5 day week. For further in-

formation apply to the Civil Service Board, City Hall, Dearborn, Mich.

Nurse for Public School System of Mount Clemens. Beginning salary \$3,200-\$3,300 depending upon training and experience. Write Box A-10. Employment Service. A.P.H.A.

Public Health Administrator. A position combining that of public health engineering and the supervision of personnel, accounting and properties in a health unit containing 57 full-time positions. The area is adjacent to the District of Columbia, has a population of 130,000, and is both rural and suburban. Salary \$4,400-\$5,060, plus a ten per cent cost of living increase. Apply to Civil Service Commissioner of Montgomery County, Rockville, Md.

Chief Health Officer for City Health Department. Department operating efficiently. Required: M.D., preferably with public health training and experience. State experience and salary expected. Apply to City Manager, Bluefield, W. Va.

City Health Officer for New England industrial city of 20,000 population; full-time position with major emphasis on child and school health program; starting salary \$6,000. Reply in detail to Board of Health, City Hall, North Adams, Mass.

Medical Director, Municipal Tuberculosis Hospital, bed capacity 115. Permanent, full time. Salary \$4,620 with full maintenance. Reply Box 583, Fall River, Mass.

Physician, as Chief of the Bureau of Tuberculosis in charge of all public health tuberculosis activities (no institutional work). Salary \$10,380 plus \$25 cost of living monthly bonus. Write to the President, Board of Health, Territory of Hawaii, Honolulu, Hawaii, by airmail.

Physician as Director City-County Health Department, Eau Claire, Wis., population 56,000; staff of 14; ideal

SANITARY SURVEY

It seems theoretically possible to control epidemics of air-borne contagion by covering dynamic foci with threshold sanitary ventilation; these foci constitute the primary sources of contagious epidemics in the community. Any attempt to tabulate the relative importance of various atmospheres encountered in experimental studies discloses a lack of trustworthy information on the essential channels of commerce in contagion. Nevertheless, in experimental design and the interpretation of epidemiological data, the relative insignificance of unblockaded channels is tacitly assumed.

Before designing a municipal water supply, the static factors which govern spread of intestinal infection, amount of pollution (I), size of aggregation (S), and effective dilution (r), must be surveyed. Control of static factors which determine effective contact rate and exposure time is not enough to prevent contagious epidemics by sanitary ventilation; dynamic factors which determine intra-aggregational reexposure linkage of generations, and the hazard of inter-aggregational linkage of exposure within the community, i.e., the chance of introduction of infection to and dispersion from social groups, must also be evaluated. A sanitary survey of the various atmospheres breathed by aggregations under observation is required to evaluate methods of control of air-borne infection. Sanitary discrimination in

the dynamic control of air-borne contagion is even more essential than in the static control of water- or milk-borne infection.

Kimble Blue Line "EXAX" Flask No. 28010 and Pipette No. 37000.

Retempered...Retested...READY ...to meet your most exacting demands

• Clinical and Scientific laboratory personnel have shown such preference for Kimble Blue Line "EXAX" graduated glassware that it has become America's favorite brand.

We can think of no better endorsement of "EXAX's" high quality...its ability to function in a great range of exacting assignments with uncompromising accuracy.

Every piece of Blue Line "EXAX"

is thoroughly retempered after forming to give added strength and durability. Every piece is retested...making doubly sure that it conforms to the high accuracy standard to which it is calibrated.

You can order Kimble Blue Line "EXAX" glassware with every confidence in its accuracy, dependability and uniform high quality. Consult your laboratory supply dealer.

For assurance, look for the Kimble K—the visible guarantee of invisible quality.

little or no pasture available, and nearly all the feed is brought in from other places. The sources of the feed for the cows are scattered over thousands of miles. Although the chief item, hay, is trucked in from the nearby Imperial and San Joaquin Valley, grain comes from northwestern United States, soy beans from the mid-West, copra meal from the Philippines, and molasses from Hawaii.

Because of the high cost of feed and land, almost all of the cows are imported from areas where pasture is available. They are usually bought as at least 3 year old animals, or so-called "second calf heifers." Although most of them are raised in California in the San Joaquin and Sacramento Valleys, many come from Oregon, Washington, Idaho, Montana, Utah, and Colorado.

Because of the lack of pasture the cows are concentrated in pens at most dairies and the considerable manure which accumulates in the pens is removed by scraping it with a bull dozer to the center of the pen where it is loaded into trucks and hauled away to fertilizer plants.

The dairies themselves consist of pens, an open milking barn, a closed feed barn, and piles of baled hay protected on the top against rain. Although most of the population in the area is concentrated in towns of a few thousand, there are many residences quite close to the dairies, and there are occasional dairies in the towns. Over 400 dairies are to be found here, and few people can travel far from their homes without passing one or more of them.

Methods of Investigation—

Through the cooperation of local physicians the names of persons who had undergone recent febrile attacks were obtained. Cases of virus pneumonia were especially sought. These people were then visited, interviewed, and

blood samples were taken. As might have been expected in the spring, upper respiratory infection provided the principal group of illnesses to be differentiated from Q fever. This differentiation could be done in most cases by taking a history of the disease and asking specific questions about upper respiratory symptoms. The presence of sore throat, running nose, and severe cough were valuable in making a diagnosis of upper respiratory infection. The complement-fixation test was of great help in arriving at a diagnosis of Q fever.

Complement-fixation serum tests were done with the technic described by Bengtson¹ with antigen prepared by method II² from yolk sacs infected with the Italian (Henzerling) strain of *Rickettsia burneti*. Results are given as the highest dilution at which 3+ to 4+ fixation was seen. Samples of blood collected in California were shipped by air mail to the laboratory in Bethesda, Md., where the sera and clots were separated. The clots were used when indicated for attempted isolation of rickettsiae. Certain precautions were taken for shipment, stoppers were fastened down securely with adhesive tape in order that they could not be loosened by the low pressures encountered in air transport, and the mailing containers were packed tightly with cotton in order to prevent breakage.

The Diagnosis of Clinical Disease in Human Beings—

Table 1 lists the clinical cases of Q fever found by preliminary investigations. The patients seen by physicians not familiar with Q fever were ordinarily diagnosed as "virus" or "atypical" pneumonia. Pneumonitis was demonstrated when roentgenograms were done.

The diagnosis of Q fever in each case was based on a typical clinical history with confirmatory laboratory findings. The typical clinical history was the same

established in yolk sacs of hens' fertile eggs by passage from guinea pigs.

Epidemiological Features of the Clinical Cases in Human Beings—

Table 1 shows that the age of the clinical cases studied varied from 15 to 62 years. Twelve males were involved, as compared to 5 females. The cases occurred from November, 1946, to May, 1947, and were still occurring in October, 1947. It seems reasonable to assume that Q fever has been occurring here for some time. As yet no seasonal incidence is apparent.

The striking feature of the epidemiology is its peculiar relationship to dairies. It can be seen that in all of the cases except two a history was obtained of having visited dairies or of having lived near them. And, as has been mentioned, it is difficult to travel far in this region without passing cow pens. Yet none of the patients had been actually employed by a dairy, and most of them had probably not come within 10 to 20 feet of a cow, so that their contact with cows was more remote than that of the dairy workers which are considered next.

Serologic Studies of Persons Not Clinically Ill With Q Fever—

We have examined sera of many persons from outside the laboratory in the past and our experience has been that

until actual cases of Q fever were encountered in epidemics, the sera were uniformly negative. The sera of patients undergoing Q fever have given clear-cut results, most patients developing antibodies to high titer during the course of their illness. However, the results on sera of persons from the milk shed area were distinctly different, as will be seen from examination of Tables 2, 3, and 4.

6 OUT OF EVERY 10 **MEASLES** CASES
WILL OCCUR IN THE NEXT 3 MONTHS!

ARE YOU READY?

All you need by way of proof that measles are upon you is the significant 10-year graph below!

And all you really need to meet the emergency is—plenty of Immune Serum Globulin, Cutter—to make measles easier on everyone concerned. Fractionated from normal human plasma pooled from fresh venous whole blood, Immune Serum Globulin offers these particular advantages for the prevention or modification of measles:

160 mgm. gamma globulin per cc.

In measles serum, it's the concentration of gamma globulin that counts. The known and constant potency of Immune Serum Globulin, Cutter, permits low volume, adjustable dosage.

Contains no placental material

Immune Serum Globulin, Cutter, causes no side reactions, is non-pyrogenic. Easily recognizable—it is water clear; hemolysis-free.

Each 2 cc. vial of this concentrated homologous protein contains antibodies equal to 40 cc. original normal serum. Dosage is determined as follows:

| | |
|--------------------------------|--|
| For prevention— | } intramuscularly, per pound body weight |
| 0.1 cc. Immune Serum Globulin | |
| For modification— | |
| 0.02 cc. Immune Serum Globulin | |

For more complete information on Immune Serum Globulin, Cutter, write Dept. 8, Berkeley 1, California.

Percent of measles cases by months from
U.S. Public Health records, total cases
1935-1945—100%

It is doubtful whether we may attribute this improvement to the use of the confidential death certificate, since proprietary hospitals in the other boroughs of the city, which continued to use the open certificate, recorded an equal if not greater improvement. Moreover, the limited data for municipal hospitals closely approximate those for proprietary hospitals, though it should be noted that for each of these sources the recorded improvement may have been due to sampling fluctuations.

The fact that the confidential method has not proved more effective than the open appears to be confirmed by the trends in the official mortality statistics. If syphilis was completely reported, the level of the recorded death rate would be almost doubled. Even if it is assumed that only one-half of these deaths are affected by the form of certification, the rate should increase by almost 50 per cent. It is apparent from Figure 1 that the introduction of the confidential certificate in Manhattan in 1939 has had no such effect. The trend for Manhattan closely paralleled the trend for the balance of the city; it was upward until 1938-1939, and downward thereafter. Moreover, what at the time appeared to be a significant rise in the death rate in Manhattan from 1938 to 1939, now appears to have been a combination of a chance downward fluctuation in 1938 followed by one in the opposite direction in 1939. Finally, a special analysis of deaths which were reported from Manhattan in January, 1947, the ninth year in which the confidential certificate was used in that borough, reveals no evidence that the "closed" certificate has resulted in better statistics. Of 42 deaths charged to syphilis, 37 were reported from municipal or state hospitals, and 5 from voluntary or proprietary hospitals; none from persons who died "at home." Although it is possible that none of the deaths which occurred "at home"

were due to syphilis, it is more likely that some did occur but were not reported.

How then may we account for the apparent improvement in the reporting of the mortality from syphilis and the upward trend in the death rate through 1938-1939? It seems fairly certain that these phenomena resulted from the intensive educational and clinical programs to bring syphilis under control which were launched by the Department of Health in 1935. Thus, in its annual report for 1937, it was stated that "the recorded death rate from syphilis is increasing due no doubt to more accurate reporting on death certificates." The effectiveness of the campaign probably resulted in a temporary increase in the recorded death rate, followed by a sharp decline after 1939. A similar trend was recorded in Philadelphia and in other communities following their inauguration of campaigns against the venereal diseases.

Puerperal Infection (140, 142a, 145a, 147)—Numerically, puerperal infection is only a minor factor in mortality. In recent years, fewer than 100 deaths have been annually attributed to this condition in New York City. However, it is probable that the disease is significantly understated in official mortality statistics since only three-fourths (74 per cent) of the deaths from puerperal infection were so charged for the cases in this study (Tables 1 and 2). Judged by the relatively small number of cases studied, the confidential method does not appear to be effective in improving the accuracy of these statistics (Table 5).

Diabetes Mellitus (61)—Diabetes is the only major cause of death found to be underreported on death certificates. Of the 394 deaths assigned to this condition, 318, or 81 per cent, were "properly" recorded. In 54 cases, death was attributed to cardiovascular-renal diseases, and 22 deaths were

tary hospitals were properly charged in 1939 and 1941 when the closed certificate was used. This is the same extent of agreement between hospital case histories and death certificates as was found for 1937-1938 when the open certificate was used. The mortality statistics for New York City, which are shown graphically in Figure 1, confirm this finding. Moreover, judged by the data in the second and third tiers of Table 6, diabetes was not more frequently mentioned when the statement of cause of death was made confidentially, than when it was certified on the open certificate.

Appendicitis (121)—Official statistics apparently understate the true extent of the mortality from appendicitis. Of the 406 deaths from this condition, only 344 or 85 per cent were assigned to appendicitis on the basis of the cause-of-death statements on mortality records. An additional 44 deaths were charged to diseases of the gall bladder and other parts of the digestive system, 12 to non-malignant tumors, and 6 to various other conditions. At the same time, 10 deaths apparently due to other diseases were charged to appendicitis (Table 1). Thus, only 87 per cent of the mortality from appendicitis was recorded for this group of persons who died in municipal and proprietary hospitals (Table 2).

In planning the study, it was not expected that appendicitis would be found to be significantly understated on death records. As a result, the data were not tabulated in a manner which would permit one to ascertain whether this de-

ficiency results from the omission of the condition from the death certificate or whether it is effected by the addition of other conditions which take precedence according to joint cause assignments. Judged by the data which are available for proprietary hospitals, appendicitis was more accurately charged as the primary cause of death in Manhattan during 1939 and 1941 than during 1937-1938 (Table 7). In contrast, proprietary hospitals in the other boroughs recorded appendicitis less accurately in 1939 and 1941 than in the preceding years.

It should be noted, when interpreting these data, that the changes for both Manhattan and the other boroughs are not greater than those which might occur due to sampling fluctuations. Therefore, since the trend in the recorded mortality from appendicitis for Manhattan closely paralleled that for the other boroughs of the city (Figure 1), it is improbable that the confidential method has affected the accuracy with which the condition is reported on death certificates. A probable factor is that the discrepancies arose primarily because of the lack of care with which the statements of cause of death were made on the certificates. The fact that deaths certified by internes were least accurately recorded (Table 2) appears to support this hypothesis. One should not overlook the possibility, however, that some physicians do not report appendicitis when it is the true cause of death, if its mention reflects unfavorably upon their professional ability.

A LOT OF GROWING TO DO

This is a big country and to furnish nation-wide telephone service, the Bell System has had to be big for a long time. But in the last few years it hasn't been nearly big enough.

Even though we've broken all records and added more than 6,000,000 new telephones in the past two years, there are still about a million orders for service that we haven't

been able to fill because of lack of equipment, switchboards, cable and buildings. Many more Long Distance circuits also are needed.

It will take time and a lot of money to make the Bell System big enough for the nation's needs but we're on our way—in a big way—to giving you more and better service than ever before.

BELL TELEPHONE SYSTEM

malignant causes on death certificates.¹⁸

While the procedures followed are not similar, our data confirm these findings. Of 1,229 deaths from cancer, 1,176, or 96 per cent, were "properly" certified on death records. The other 53 deaths were charged to various other conditions (Table 1). Offsetting these "misses," 60 deaths were attributed to cancer on death records in disagreement with the facts available in hospital charts. For the cases included in this study, therefore, the official mortality statistics accurately reflected the extent of the mortality from cancer. This was true for deaths which occurred in proprietary hospitals as well as those reported from municipal hospitals (Table 2).

In view of the above, it is highly improbable that cancer is understated in the mortality statistics for New York City. It would not be expected, therefore, that the confidential method would have any effect on the accuracy of these statistics. This fact is confirmed by the data in Table 9, and the trends in the mortality from cancer shown in Figure 1.

Mental Disease—Because of the small number of cases, mental disease (84) as a primary cause of death is included with the "All Others" group in Tables 1 and 2. Analysis of the extent to which mental diseases (84, 162a, pt. 77b, 150b, 30b) are mentioned on death certificates, whether or not the conditions contributed to death, reveals no

evidence that they were more completely recorded on the confidential than on the open certificate.

External Causes (78, 79, 163-198)—Among the 7,330 deaths studied, 17 cases were found in which an external cause appeared in the hospital case history but was not reported on the death certificate. Of these cases, 12 deaths should have been charged to the external cause, and 5 to other conditions. As may be seen from Table 1, one-half of the 12 deaths from external causes were charged to cardiovascular-renal diseases on death certificates, 2 to respiratory diseases, and 1 to each of four different conditions. Evaluation of these cases indicates that most if not all of these differences involve intentional avoidance of medical examiner action. As such, it is doubtful whether any form of reporting can be expected to eliminate these discrepancies.

Operations Performed—The completeness with which operations are reported on death certificates has a major effect on the accuracy of mortality statistics. It is pertinent, therefore, to ascertain whether operations were more completely reported on the confidential than on the open certificate.

Analysis of the data for 5,606 white decedents from proprietary hospitals reveals that operations had been performed on 2,147, or 38.3 per cent, of these patients. Of these, 2,097, or almost 98 per cent, were reported on official death records. While the fre-

rience, and written tests. The consensus seemed to be that the written tests for entering positions should receive very heavy weighting; that the oral interview should carry least weight of the three, perhaps 20-30 per cent; and that the rating of training and experience should carry a generous weight for "upper bracket" administrative positions, much less for first level jobs.

In conclusion, Mr. Moore summed up the situation by saying

The establishment of a minimum qualification for admission to practise a profession, does not, in and of itself, eliminate from merit system selection those people who are

not fitted to carry the specialized job. If some other device is not used, the appointing authority may find himself called on to choose the best of three undesirables. Written objective-type tests, properly constructed according to adequate job specifications, are suggested as appropriate and desirable instruments for ranking candidates

He reminded the audience that the Merit System Service of the A.P.H.A. is interested in all steps in selecting personnel. It can suggest the names of persons to serve on oral interviewing boards, and as advisers for assisting with the rating of training and experience, as well as supply the written objective-type tests under discussion

Kimble Blue Line "EXAX" Flask No. 28010 and Pipette No. 37000.

Retempered...Retested...READY ...to meet your most exacting demands

● Clinical and Scientific laboratory personnel have shown such preference for Kimble Blue Line "EXAX" graduated glassware that it has become America's favorite brand.

We can think of no better endorsement of "EXAX's" high quality...its ability to function in a great range of exacting assignments with uncompromising accuracy.

Every piece of Blue Line "EXAX"

is thoroughly retempered after forming to give added strength and durability. *Every* piece is retested...making doubly sure that it conforms to the high accuracy standard to which it is calibrated.

You can order Kimble Blue Line "EXAX" glassware with every confidence in its accuracy, dependability and uniform high quality. Consult your laboratory supply dealer.

For assurance, look for the Kimble K—the visible guarantee of invisible quality.

KIMBLE GLASS TOLEDO 1, OHIO
Division of Owens-Illinois Glass Company

Our study of the state health department's attitudes and needs led to much the same conclusions just presented. In addition, each bureau and division in the state department felt it would like to develop educational and training programs in relation to its own service programs. This was especially true of the Division of Preventive Medical Services which includes Maternal and Child Health, Public Health Nursing, Tuberculosis, Venereal Disease, Chronic Disease, and Industrial Disease services. The Bureau of Health Education wanted consultation from us as to literature, film, and library facilities, and the Division of Local Health Services wanted to have some consultation service available to local health departments for development of local mental health programs. The administrative personnel of the state department felt they needed a group of seminars to acquaint them with knowledge about normal emotional growth and development as applied to public health practice, some discussion on the problems of personnel, and the emotional aspects of administrative practices.

A PLAN FOR ACTION

These studies enabled us to draw up a plan of action which, it was hoped, would answer some of the needs as expressed and provide us with a means to test whether our ways of teaching and educating, once they were under way, were or were not meeting the needs and thus better equipping our health workers for helping their patients handle the emotional problems of living.

In the State Health Department the program is starting with a series of seminars for the top administrators. We meet informally once a week for a planned ten or twelve times. The groups are kept small—about eighteen to twenty members. The subject matter covers the following items:

1. The essentials of emotional maturity

2. The normal growth of the personality toward emotional maturity and the defenses which handle threats to the integrity of the personality

3. The emotions of illness and convalescence

4. The doctor-patient relationship

5. The nature of authority or emotional aspects of administration

Upon completion of these seminars, other series will be held with the various specialist and consultant personnel in the state department.

In two local health departments projects are under way which represent approaches toward aiding the nurses and physicians in the clinics to grow more quickly into the role of handling the emotional aspects of everyday medical and nursing practice. The Health Department of the City of Berkeley has added to its staff a pediatrician, with training in child psychiatry, who spends three half-days a week in health department work. In one of these periods this physician sees babies and mothers in a well baby clinic. The nurses of the health department rotate through this clinic every 3 months. Another half-day is given to educational programs for nurses and school counselors, and the third half-day is used for consultation with the pediatricians conducting other child health conferences. This program has been under way so recently that no evaluation of this approach is yet in order.

I also attached myself to a local health department, that of the City of Richmond. In coöperation with the health officer and his staff, a mental health teaching program has been started. We hope it will begin to meet not only the educational needs of the nurses and physicians but also become a part of the program of a busy, well rounded, overworked health department without adding to the burdens of a staff already pressed for time. Such a program should be possible within the usually limited budget of such a health department.

corporate in accordance with the pattern of our culture.

Another thing that medical workers are usually unprepared for is that parents sometimes have emotions of anger, guilt, or feelings of hostility against their children at the same time that they may have deep affection for their children. Our parents and children frequently seek for some help in understanding and accepting such feelings, and in this aspect of practice we most frequently fail to help them. To supply some of this need, which we think will also increase the health workers' understanding of emotions in adults as well as children, we are establishing what might be called a laboratory of human behavior for nurses and physicians. Here they will become a part of a nursery school staff, work closely with children, and examine their own emotional reactions to what they find in these children and parents. They will be guided in this by a staff of well trained nursery school teachers, pediatricians, and psychiatrists.

LEARNING FROM PATIENTS

Children are the best teachers in the world, if we observe and listen to them. They have constant frustrations leading to emotions of anger, sometimes hostility. They enjoy themselves simply and they normally initiate play which has much meaning for them. They form fast loyalties and are quick to detect the sensitivities and defenses in the makeup of adults. A few physicians and nurses will spend two to three months full-time, working with the nursery group under competent direction, and will be assigned one or two children whom they are to observe carefully, and try to put into writing what they observed. Under the guidance of a pediatrician, who is oriented in the emotional growth and development of children, the nurses and doctors will also spend time in the well baby, rheumatic fever, and cerebral palsy clinics, which are a part of the

hospital and the child development center. Each nurse and physician will be assigned time, at least one hour a week, to discuss with a staff member his doubts, confusions, discoveries, and feelings about what is taking place. At the same time he listens in on the parents' class and the staff discussion about the child and his family situation.

At the end of this experience it is our hope that the nurse and physician will return to the health department not experts but a better nurse and a better physician. This should come about because they will better accept themselves as agents who help people understand their feelings and problems, rather than merely telling them how to be more adequate and healthy persons. If these physicians and nurses feel such an educational experience is what they need for their own growth in their work, then we plan to expand our efforts and invite medical and nursing staff members from local health departments throughout the state to apply for this experience. These individuals, returning to their departments after such an experience, will begin to influence other local staff members and also provide a nucleus of a local staff around which inservice training programs may be started. It is our intention, once this happens, to form a small state educational team which will work through and with these workers, thus giving continual educational stimulation in the incorporation of mental health principles as part of public health practice.

What I have described to you is a beginning of an approach toward this goal. We are feeling our way along. We hope this beginning will grow into a plan that may prove practical and effective enough so that other health departments may learn from our mistakes and our successes and thus adopt it to fit the conditions and needs found in their own staffs and in their own locale.

PARKER, DAVIS & COMPANY • DETROIT 32, MICHIGAN

ing due consideration to all racial groups and organizations. Because these are working committees, emphasis is placed upon utilizing lay individuals as far as possible and making use of professional health personnel in a consultant capacity. Services of the latter are best used in planning because they usually do not have sufficient time to undertake the all-important follow-up activities. Besides, placing responsibility on lay volunteers gives them an incentive to demonstrate leadership and is a motivating force in overcoming public inertia.

Bi-monthly meetings, and special sessions as required, are held by the council. Programs are planned in cooperation with the various groups on the basis of interests and needs. This organization has provided a mechanism for discussing in a democratic manner health problems that have community concern. Also it has made possible the machinery with which to carry on follow-up activities of an educational and legislative nature which will enable us to deal more effectively with these problems.

A number of tangible results have already been achieved. They include establishing a full-time professorship in health education at the University of Hawaii, setting up a school of practical nursing under the auspices of the Vocational Division of the Territorial Department of Public Instruction, inaugurating outpatient clinic facilities in two local hospitals, sponsoring a Hawaii branch of the National Society for Crippled Children and Adults, and preparing an exhibit and booklet *The Health Story in Hawaii*.

Hawaii's health story merits special consideration because it is unique in our experience. Its purpose was twofold: to compile and present in a readable and interesting manner factual information on health in Hawaii; and to acquaint people throughout the Territory and on the mainland with health activities in

the islands. The project was sponsored by the Public Health Committee of the Chamber of Commerce of Honolulu in cooperation with the Oahu Health Council. The former organization initiated the idea and subsidized the costs entailed in its preparation.

The chairman of the Community Education Committee of the Oahu Health Council headed the special exhibit committee. Other members included representatives of the Public Health Committee of the Chamber of Commerce of Honolulu and its staff, Territorial Medical Society, Territorial Board of Health, Hawaii Visitors' Bureau, and Holst and Cummings advertising agency. The first problem which confronted them was how to portray the desired overall picture of health work in the Territory. It was finally decided to prepare a small booklet of approximately one hundred pages with photographs and descriptive copy.* It was also agreed that the content should feature health programs rather than the specialized work of individual agencies because it seemed more logical to tell what is being done rather than who is doing it.

The first step was the preparation of an outline allocating a certain percentage of space to each activity. Then a script was written showing why the percentages were made and outlining the points to be covered in each picture and page of copy. This material was circulated to each health council member and to other interested persons throughout the Territory. A revised outline embracing the suggestions and criticisms received was then drawn up, and work schedules were made out for photography and final copy. Fourteen agencies and individuals contributed photographs; sixteen organizations provided consultant services and other materials.

Simple Goiter in Colombia*

HORACIO PARRA, M.D.

*Nutrition Division of the Coöperative Health Service of Colombia and
The Institute of Inter-American Affairs, United States*

SIMPLE goiter is a problem of Colombian pathology which is so prevalent and of such long existence that it has been treated by naturalists, physicians, and even writers and folklorists.

In 1808, Francisco José de Caldas, outstanding Colombian naturalist and martyr of our independence, mentioned repeatedly the problem of simple goiter in his scientific works. He apparently was the first man of learning who attributed the disease to drinking water which has an excessive quantity of lime and heavy minerals.

In 1810, Don Joaquín Camacho studied the distribution of simple goiter in Colombia. He noted the fact that in Bogotá the disease was frequent in the convents, where the source of the drinking water was a well or an artesian well—generally quite hard water. Moreover, though the efficacy of iodine had not as yet been discovered, Camacho found the lack of endemic goiter among the inhabitants of the seacoasts significant and attributed this fact to the use of sea salt.

Later in 1831, the French naturalist Boussingault observed the presence of simple goiter in human beings and animals in localities where cooking salt very low in iodine content was used. He, therefore, advised the Government of Colombia to establish the use of salt from natural iodized sources as a pre-

ventive measure against this endemic disease. So it was that, from 1831 until 1947—a lapse of 136 years—the country of Colombia has delayed in putting into practice the recommendation of this learned Frenchman.

A recent study carried out by Socarrás in 1942 on the registration of the recruits of the "Sanidad Militar" indicated that 10 per cent of the 153,000 prospective recruits were rejected from military service because of simple goiter.

On the basis of these antecedents, the Nutrition Department of the S.C.I.S.P. has carried out the following plan of study:

1. Incidence of simple goiter in Colombia
2. Distribution of the endemia
3. Propagation and extension of simple goiter
4. Causes, contributory factors, and the sequels of the disease
5. Preventive measures
6. Manufacture of artificially iodized salt
7. Financing of a project for the artificial iodization of salt and the creation and maintenance of the Instituto Nacional de Nutrición (National Nutrition Institute).

The following is a summary of these activities:

1. In order to determine the incidence of simple goiter in Colombia, the school age group was chosen among the various population classifications. The school group possesses three very necessary characteristics: first, it is representative of the general population; second, it is the most susceptible to preventive and curative treatments; and third, as a group for investigation purposes, its examination is easy and

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

The above graph of measles incidence based on U. S. Public Health figures for a ten year period is supported by current reports of present measles incidence.

The measles peak is
RIGHT NOW!

You can prevent or modify measles
without fear of side reactions* with

IMMUNE SERUM GLOBULIN—CUTTER

Right now, when 60% of all measles occur, is a good time to remember Cutter Immune Serum Globulin, a product of human blood fractionation.

In measles serum, it's the gamma globulin that counts. And Immune Serum Globulin—Cutter, contains 160 mgm. gamma globulin per cc. This known and constant potency permits low volume and adjustable dosage.

Second in importance is the blood source—fresh, virus-free whole blood in the care of Cutter. Immune Serum

Globulin contains no placental material.

You can always tell Immune Serum Globulin—Cutter—it's water clear and hemolysis-free. Each 2 cc. vial contains antibodies equal to 40 cc. of original normal serum.

For more information, write Dept. 8, Berkeley 1, California, or ask your Cutter representative.

Mass Control of Dental Caries Through the Use of Domestic Water Supplies Containing Fluorine

FREDERICK S. MCKAY, D.D.S.

Colorado Springs, Colo.

BASED upon the generally prevailing rate of decay and tooth loss the forecast for the future is grim to the point of seriousness. A prediction published by an authoritative source as recently as June, 1947,¹ puts it as follows:

"It is estimated that . . . the 3,400,000 children born in 1946 . . . at 16 years of age will (each) require 7 fillings and 2 extractions and that 40 per cent of those reaching 40 years of age will require dentures."

Evidence collected during the past several years has established that the

continuous use of a domestic water supply containing even as low as approximately 1 p.p.m. of fluoride, during the period of tooth calcification, will bring about a mass reduction in the dental decay rate. As will be apparent later in this paper the conditions existing in fluorinated districts are in complete disrelation with the prediction quoted just above.

The evidence up to the present time has been derived almost wholly from examinations of children. There has been almost no information as to the dental

TABLE 1

Summary of observations on 400 Colorado Springs (Colo.) natives having dental fluorosis

| Age Groups | 10-14 | 15-19 | 20-24 | 25-29 | 30-34 | 35-39 | 40-44 | 45 and above |

FREDRICK S. MCKAY, D.D.S.
COLORADO SPRINGS, COLO.

July, 1947

Table 2 was computed from charts compiled prior to those used as Tables 1 and 3 in this paper which accounts for the slight variations.

40 Years Growth in 2 Years

The telephone was forty years old before there were six million Bell telephones in this country. Now there are twenty-nine million. The last six million have been added since these little tots were born—in about two years instead of forty.

But growth is not the only measure of the increased value of your telephone service. Many new developments are extending its scope and usefulness.

There is the extension of telephone service to automobiles, trucks, buses, boats, trains and airplanes.

There is the \$200,000,000 program to extend telephone service in rural areas. Today there are more rural telephones than

Then there is coaxial cable, no thicker than your wrist, which can carry 1800 Long Distance calls at one time. And along with it is a new system for transmitting telephone conversations by super-high-frequency radio waves. Both are designed so they can be used for Television as well as Long Distance calls.

And research on new electronic devices, now under way in Bell Telephone Laboratories, brings still wider horizons of electrical communication within view.

It's all a part of progress and our constant effort to make telephone service better and more useful for every telephone user.

Senate Bill Provides Aid to Medical Education

Early in May, Senator Elbert D. Thomas of Utah introduced a bill providing for federal subsidies to schools of medicine, dentistry, nursing, and public health, and for scholarships for qualified students. The bill has been referred to the Senate Committee on Labor and Public Welfare and is numbered S. 2588.

According to the *Washington Report on the Medical Sciences*, federal grants up to \$20,000,000 a year are authorized for medical schools; \$8,000,000 for dental schools; \$18,000,000 for nursing schools, and \$2,000,000 for postgraduate schools of public health. In addition, federal grants up to 50 per cent of the cost of new construction of physical facilities are authorized. To qualify for grants, schools must not impose unreasonable restrictions against admission of nonresidents or bar applicants on the basis of race, creed, color, or national origin (special provision is made for in-

stitutions in those states having racial segregation laws). State and national scholarships are provided for, the former in medicine, dentistry, nursing, and public health, and the latter in medicine alone. Holders of national medical scholarships would be pledged to serve one year in federal status for each two academic years of his scholarship. Or he would be permitted, in lieu of government obligated service, to practise in an area where a state health authority considered there to be a shortage of physicians. State scholarships include tuition and books. The other type offers, in addition, a stipend of \$90 per month. Final paragraph of S. 2588 prohibits any federal agency or officer to "exercise any control over, or prescribe any requirements with respect to, the curriculum or administration of any school, or the admission of applicants thereto."

chemical industry is to decide which products must be examined, as the toxicological facilities available today do not allow universal examination. The workers, especially those engaged in research and pilot plant activity, must be subjected to stringent industrial hygiene and medical control as this class of employee is exposed to products about which usually little is known.

In discussing the toxicology of the newer metals it is, perhaps, more accurate to use Fairhall's description and refer to them as metals which have become important industrially in recent years.² The most prominent members of this group are beryllium, cadmium, tellurium, uranium, and vanadium. There is no common group action or symptom complex. Very little is known about some of these substances, because as yet they have been used in limited amounts in restricted work or have not been recognized as having distinctive physiological properties.

Beryllium has been reported as the causative agent of two types of lung condition. One is a chemical pneumonitis which occurred in men working with fluorescent powders. Some of the beryllium salts, notably the sulfate, hydrolize easily and extensively so that the local production of sulfuric acid in the lung could be expected after the inhalation of the dust.

Reports of a number of cases of what is termed pulmonary sarcoidosis have been appearing in the literature in the past few years. These workers were exposed to beryllium powder in the fluorescent lamp industry. The causative relationship has not been worked out and extensive laboratory investigations on this point are under way.

Cadmium has been responsible for a considerable number of fatalities due at first to a non-recognition of its physiological action but later due to a non-recognition of its presence on the parent metal. Cadmium coatings of vessels can

cause poisoning when they are used as food containers. If a cadmium-coated article is subjected to a cutting or welding torch, cadmium oxide fume poisoning may result. This takes the characteristic form of a delayed pulmonary edema similar to nitrous fume poisoning.

Cobalt is used chiefly in the production of magnets in conjunction with nickel and aluminum and as a bonding agent in metal carbide tips for the tool and die industry. Considerable physiological and pharmacological work has been performed showing that cobalt administration produces polycythemia. There have been no reports of clinical or industrial poisoning, however.

Tellurium is a metal that was found to improve the hardness and machineability of steel. Cases of tellurium poisoning have been reported due to excessive fumes. The symptoms are anorexia, lassitude, nausea, and vomiting. The main diagnostic feature is a garlicky odor of the breath and urine. These cases have not proved particularly serious.

Uranium is a poisonous element and causes kidney damage similar to other heavy metals, such as mercury. Chronic nephritis, as a result of exposure to this metal, occurred as early as 1854. There have been no reports published of any ill effects in workers engaged in purifying this material for use in the chain reacting piles.

Vanadium is a metal that has markedly increased in use as a catalyst and a component of steels. There is considerable discussion about the degree of toxicity it possesses. Pulmonary edema and pneumonitis have resulted from inhalation in animals. In workers the lung changes have been limited to an asthmatic bronchitis.

High frequency radiations, popularly called microwaves, include that range of the radio frequency spectrum from approximately 1,000 megacycles (1,000,000,000 cycles per second) to 30,000

DORLAND LISTS 47 VARIETIES OF

...GET TRIPLE-ACTION RELIEF*

WITH CUTTER DERMESTHETIC OINTMENT

Everything from "alkali" to "winter" causes the itch complaints that reach your professional ear—but regardless of etiology, the physiology of each itch is the same.

That's why the use of Dermesthetic Ointment for symptomatic relief is an excellent prescription as the first step in treating every one of these 47 itch varieties. Here's the type of relief it offers:

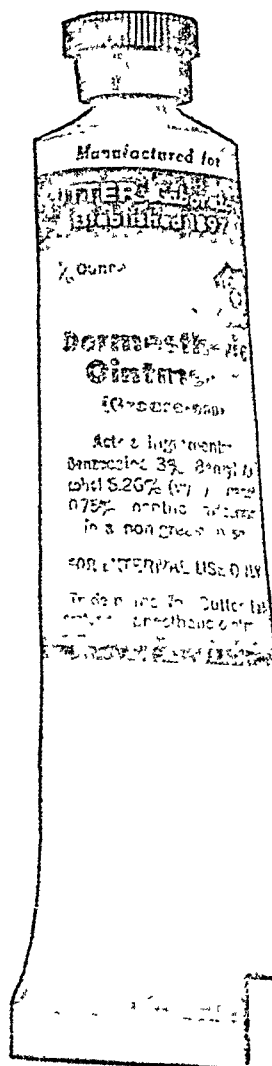

FAST: Dermesthetic Ointment contains benzyl alcohol, which works fast but doesn't last . . .

OVERLAPPING: Phenol offers intermediate relief—with moderately prolonged effect . . .

PROLONGED: Benzocaine, which has already begun to soothe affected areas, continues to relieve the itching over a prolonged period.

Nevertheless, it does not dissolve and spread oil-soluble irritants. It can be removed easily and will not stain skin or clothes. We will welcome your request for clinical samples.

*24 hours tested as a bactericidal agent, Dermesthetic Ointment with its Benzyl alcohol and Phenol is fast-acting. This is due to its combination with the benzocaine which helps soothe the skin from scratching.

Itches in Industry: Physicians have long recognized skin irritations as one of the leading "occupational hazards" of most workers, yet late studies show itching to be caused by an even greater mass of offenders than had previously been suspect. In many of these industrial rashes and itches, Cutter Dermesthetic Ointment is found to offer immediate relief. While not recommended as a cure, it does stop scratching, thus helping a condition to heal normally.

Cutter Laboratories, Berkeley 1, California

in research and development. However, private industry and governmental agencies are spending annually on scientific research over \$1,200,000,000. This work will narrow the gap between the visionary products of today and the actualities of tomorrow, and will furnish us a constant source of associated health problems.

Training in Engineering Aspects of Atomic Energy

The Massachusetts Institute of Technology announces a school for graduate training in the engineering aspects of atomic engineering. Work will be done in the production plants of the Atomic Energy Commission operated by the Carbide and Carbon Chemicals Corporation at Oak Ridge, Tenn.

"The purpose of the school is the education of graduate students in several fields of engineering under a program which is designed to develop their ability to apply basic

principles to the solution of technical problems encountered in industry with emphasis on the engineering aspects of atomic energy."

Admission to the new school is restricted to graduate students in the several engineering departments of the Institute who have been in residence at M.I.T. at least one term and are U. S. citizens. Further information can be obtained from Professor William A. Reed, Massachusetts Institute of Technology, Boston, Mass.

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
BOSTON, MASS., NOVEMBER 8-12, 1948

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1948, the total membership of the Association was 11,124, including 1,913 Fellows, or 17 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been in course a degree of Doctor of Medicine, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, or Doctor of Medicine with at least two years of graduate study in public health education, Master of Public Health, Doctor of Public Health, or other equivalent

degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Appli-

*Kimble Laboratory Thermometer No. 43504;
Hydrometer No 31658; Hydrometer Cylinders No. 20060*

THE KIMBLE ORGANIZATION is unique in the precision of its Kimble-developed automatic production units . . . its skilled craftsmen . . . and the driving urge to translate precision and skill into glassware of the highest possible quality.

Kimble Thermometers and Hydrometers are precision-made and calibrated by the finest equipment of its kind. They are thoroughly tempered and aged to insure stability...they

are individually retested before shipment . . . are guaranteed within accuracy limits as specified by the National Bureau of Standards.

A complete variety of standard types is now listed in the Kimble Catalog of Laboratory Glassware. Order by number for prompt deliveries from your laboratory supply dealer. Special types can be furnished on reasonable notice.

Journal (p. 1049). At that time the first issue of the Dermatology and Venereology Section had been published. Now Vol. 1, No. 1, of Section IV on Medical Microbiology and Hygiene, has appeared, in January, 1948. Among its American board of editors are Drs. Charles Armstrong, Martin Frobisher, Jr., Hugh R. Leavell, Ernest L. Stebbins, and C.-E. A. Winslow. The material in this section is divided into three main classifications: Medical Microbiology, Hygiene and Public Health, and Medical Entomology and Medical Parasitology.

At the same time the first issue of Section XV on Tuberculosis appeared. Among its editors is J. Burns Amberson, M.D.

All but one of the fifteen sections have now begun publication.

ANOTHER MEDAL FOR DR. CORI

Dr. Carl F. Cori, a Nobel Prize winner and winner of a 1946 Lasker Award of the American Public Health Association, recently received the 1948 Willard Gibbs Medal of the Chicago Section of the American Chemical Society for his achievements in research on processes by which the human body converts sugar into energy. Dr. Cori is Professor of Biochemistry in the Washington University School of Medicine, St. Louis, Mo.

COMMITTED TO STUDY FEDERAL GOVERNMENT'S MEDICAL AND HOSPITAL FACILITIES

The Commission on the Organization of the Executive Branch of the Government, which is headed by Herbert Hoover, has announced the following members of a committee which will investigate the government's medical and hospital services:

Tracy S. Voorhees, president of Long Island College Hospital, Brooklyn, N.Y., chairman; Drs. R. C. Buerki and O. H. P. Pepper (University of Pennsylvania),

Hugh J. Morgan (Vanderbilt), Allen O. Whipple (Columbia), W. C. Menninger (Menninger Foundation), Ray Lyman Wilbur (Stanford), Frank R. Bradley (Barnes Hospital, St. Louis), Michael DeBakey (Tulane). Also on the committee are Charles F. Rowley, former trustee of Massachusetts Investors Trust; Henry Isham, president of Chicago's Passavant Hospital; Dr. Paul R. Hawley, Chief Executive Officer of the National Organization of Blue Cross Hospital Service Plans and Blue Shield Medical Service Plans; and Rear Admiral Joel T. Boone, secretary of the special board now investigating armed forces medical and hospital services.

MORE BABIES AND THEY LIVE LONGER

The National Office of Vital Statistics recently announced a new low infant mortality record for the United States in 1947 of 32.6. The number of live births registered also set a new high record of 3,720,000. The provisional general death rate for the country was 10 as compared with the lowest recorded, 9.9 in 1946.

CHANGES IN STAFF ASSIGNMENTS, U. S. PUBLIC HEALTH SERVICE

Several changes have taken place in the staff of the U. S. Public Health Service in Washington following the assumption by Dr. Leonard A. Scheele of his duties as Surgeon General.

The Federal Security Administrator has nominated for the rank of Major General, Drs. C. L. Williams, Sr., Chief of the Bureau of State Services, and R. C. Williams, Chief of the Bureau of Medical Services. Also nominated for the same rank was Dr. Rollo E. Dyer, Director of the National Institute of Health.

Dr. John R. Heller, who has served as Chief of the Division of Venereal Diseases since 1943, has been appointed Director of the National Cancer Institute, Bethesda, succeeding to the post

appointed anesthesiologist of the Department of Obstetrics of Johns Hopkins, Baltimore, effective July 1. He will be on special assignment from the U. S. Public Health Service to conduct a 5 year program in the relief of pain in childbirth.

CLARENCE I. STERLING† has been named Director of the Health and Sanitation Division, Institute of Inter-American Affairs, Washington, D. C., to succeed RICHARD J. PLUNKETT,† who resigned to become Assistant Editor of the *Journal of the American Medical Association*.

E. J. SUNKES, DR.P.H.,* has been appointed Director of the Division of Laboratories of the State Department of Public Health, Atlanta, Ga., succeeding THOMAS F. SELLERS, M.D.,* who was recently appointed Director of the State Department of Health. Dr. Sunkes has served 26 years with the Georgia State Laboratories.

NORMAN H. TOPPING, M.D., with the U. S. Public Health Service, Washington, D. C., has been appointed to the new position of Associate Director of the National Institute of Health, Bethesda, Md.

JESSE MEUSE was recently appointed as Negro Health Educator for the Florida State Board of Health, Jacksonville. He has had many years of experience in the field of public health and teaching in public schools of Florida. As a member of the division of health information, he will work with various groups in the promotion of better health among the Negro population of the state.

JOHN MULRENNAN, Director of Entomology, Florida State Board of Health, Jacksonville, was named President of the Florida Anti-Mosquito Association, at a joint meeting of the Florida group and the American Mosquito Association, in Ft. Pierce, Fla., March 18-31.

Western States

HAROLD D. CHOPE, M.D.,* Assistant Health Officer of the San Joaquin public health district, and a former Assistant Director of the California State Department of Health, became San Mateo County, California, Health Director, as of May 1.

CHESTER A. FEE has joined the staff of the Oregon State Board of Health, Portland, as Health Information Consultant. A veteran of World War I, Mr. Fee worked as an educator in California for some years. He has been associated with newspapers and magazines as writer or editor. Formerly with the Department of English at the University of Oregon, he is best known as the author of *Chief Joseph* and other works.

Other Areas

JOSEPH N. LANOIX† has been appointed Director General of Hydraulic Services for the Government of Haiti and for the American Sanitary Mission in Haiti.

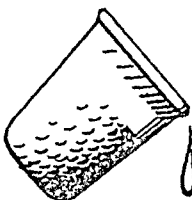

SAM H. ZIA, M.D.,† of Peiping, China, has been appointed Professor and Head of the Department of Bacteriology of the Peiping Union Medical College, effective April 1. Dr. Zia is known in the United States as a former associate of HANS ZINSSER, M.D.

Deaths

EDNA M. KECH,* Director, Division of Health Education, State Health Department in Pennsylvania with offices in Harrisburg, died recently in Florida.

CONRAD KINYOUN,* Director of the Department of Health Laboratories of Savannah, Ga., died March 31. Burial was in the National Cemetery, Arlington, Va., with full military honors.

A thimbleful of  dosage...

for a handful of baby . . . **2.5cc HYPERTUSSIS**

concentrated human anti-pertussis globulin
— protects exposed infants—treats critical
cases. When whooping cough attacks small
patients, the hazards of massive repeated
dosage present a serious problem to every
thoughtful physician.

2.5 cc Hypertussis
provides the specific
solution for therapy or
passive prevention.
The advantages
are evident:

Concentrated Potency:

- 2.5 cc concentrated by fractionation to
contain the antibody equivalent of
25 cc hyperimmune human serum.
- 2.5 cc delivers consistent gamma globulin
potency in constant measured doses.

Small Volume Dosage:

- 2.5 cc concentrated gamma globulin re-
duces dosage volume 75%—minimizes
injection trauma—permits repetition
when required.

Homologous, sensitivity-free:

- 2.5 cc clear liquid homologous protein,
Hypertussis is ready for intra-
muscular injection—avoids danger of
reactions and serum sensitivity.

For 10-fold concentration in small volume dosage
—specify **CUTTER 2.5cc HYPERTUSSIS**

CUTTER LABORATORIES • BERKELEY, CALIFORNIA

FIGURE 5—Relative densities of malaria-carrying species of mosquitoes within and adjacent to protected zones in the United States during the five World War II years.

were developed to teach the lay public simple facts about the cause, nature, transmission, and prevention of malaria, thus securing cooperation in effecting the objectives of the program.

The main malariologic shortcoming of this War Areas Program was that it was aimed only at the protection of military trainees and war workers. Thus it did not nullify foci of primary malaria endemicity unless they were near military training camps, maneuver areas, airports, shipyards, or the sites of war industrial or recreational facilities.

A third federally sponsored program which may have exercised some effect on anopheline prevalence over a considerable portion of the South is that of the Tennessee Valley Authority. This organization was created in 1933. Since then it has constructed or acquired 26 artificial impoundments along the Tennessee River and its tributaries. At maximum normal operating level, these lakes cover nearly 600,000 acres, and their total shore line extends well over

10,000 miles.²⁶ Much of the marginal area is within the limits of traditional malariousness where conditions favor the propagation of *A. quadrimaculatus*, a notorious impoundment breeder. The threat of enhanced malaria incidence was recognized early in the planning phase and, as an important element of the Health and Safety Department, a Malaria Control Division was activated. Its functions, at first investigational and operational, now consist of the development of the TVA malaria control program and the planning and appraisal of its execution in the field. The anti-larval measures utilized include reservoir preparation and improvement, water level management, larviciding, drift removal, and herbiciding—all prosecuted on very large scales. The studies of the TVA Malaria Control Division and the operations performed by it or under its technical supervision appear to have not only kept malaria from becoming a major cause of morbidity in the Tennessee Valley but have reduced to the

| More than \$3,000 | 363 | 64 | 2 |
| Less than \$2,400 | 3 | 842 | 597 |

mode, affecting 142 persons, between \$2,400 and \$2,600. Only 6 per cent received \$5,000 or more and nearly one-fourth less than \$2,400. As to regional medians, the median for Eastern and for North and South West Central states was equal to that of the country as a whole, that for the 12 Southern states lower, and for other areas higher.

Public health nursing personnel was divided into four categories—directors of public health nursing, supervisory and consultant nurses, staff level nurses, and graduate registered nurses. The three latter groups were found in the ratio of one, three, and one and one-fifth.

All but 2 of the 48 states reported salaries for directors of public health nursing. These salaries ranged from \$3,200 to \$7,375 with \$4,200 as the median. In 7 states only was the salary \$5,000 or over; in 8 states it was \$3,600 or less.

The median salary for the supervisory and consultant group was between \$3,100 and \$3,200. For the 534 reported positions salaries range from less than \$2,400 to \$5,600. However only 5 persons received \$4,800 or over, and only 33 received \$4,000 or more, while about one-third received less than \$3,000.

The ranges of salaries for the three groups of nurses in the field of public health other than directors are shown in Table 3.

State directors of dental health serv-

ices were reported for 44 states. The highest salary paid was \$7,100 in one state, a state in which the director of maternal and child health, of venereal disease control, of tuberculosis control, and of sanitary engineering were paid respectively \$7,680, \$7,080, \$8,280, and \$8,280. The median salary for dental health directors was \$5,400. Fourteen salaries were below \$5,000 and 8 were above \$6,000.

State directors of vital statistics were reported for 47 states. The salary range for this group of workers was from \$2,400 to \$8,000 while the median was \$4,500. In only 3 states was this position paid at \$6,000 or more and in 15, less than \$4,000.

Nutritionists. Salary reports were received for approximately 100 nutritionists on the staffs of state health departments. For these the median salary was \$3,000-\$3,100, affecting 14 persons. Only 6 persons received more than \$4,000 and 18 received less than \$2,700. Nearly half of the total number received between \$2,700 and \$3,200. Because of the small numbers involved this group was not classified either by state or by region.

It is now expected that similar studies will be made annually. It is hoped that the experience of this first study can be used to refine job definitions and classifications so that comparisons will be meaningful in terms of training and responsibility.

Who's Tops in Telephones? It's U.S.

There are more telephones in this country than in all the rest of the world put together. The United States has one telephone for about every four people, compared to one telephone for every ninety people for the rest of the world.

Sweden comes closest with one telephone for every five people. In the British Isles there's one telephone for every eleven people. In Russia the estimate is about one in a hundred.

New York leads the world's cities with the most telephones. It has 2,600,000—more than in all of France. In relation to population, San Francisco is on top with about one telephone for every two people. Washington ranks a close second.

And we're still building and expanding at the fastest rate in history. The value of telephone service is increasing constantly.

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING
 AMERICAN PUBLIC HEALTH ASSOCIATION
 BOSTON, MASS., NOVEMBER 8-12, 1948

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Harle V. Barrett, M.D., 408 South Second St., Independence, Kan., Montgomery County Health Officer

Leslie D. Bent, 65 Chestnut St., Montclair, N. J., Asst. Health Officer, Montclair Dept. of Health

George J. Boines, M.D., 511 N. Rodney St., Wilmington 99, Dela., President, City Board of Health

Jose Cerra-Quinones, M.D., U.S.P., Naguabo, Puerto Rico, Health Officer, Insular Dept. of Health

R. A. Clanton, M.D., 606 Marg'n St., Grenada, M.ss., Medical Director, Grenada County

Samuel Klauber, M.D., Health Dept., Mayaguez, Puerto Rico, Supervisor, Western District Health Dept.

Cesar J. Lesaca, M.D., M.P.H., 615 N. Wolfe St., Baltimore 5, Md., Medical Officer, Tuberculosis Control (Philippine Bureau of Health)

Dr. A. H. Lockhart, U.S.P., Cayey, Puerto Rico, Director, Cayey Health Unit

Michael R. Macdonald, M.D., C.M., D.P.H., 103 Charlotte St., Sydney, N.S., Canada, Divisional Medical Health Officer, Dept. of Public Health, Province of Nova Scotia

Max B. McQueen, M.D., M.P.H., District Health Unit, Lewiston, Idaho, Director

Cesar A. Negrette, M.D., Maricao, Puerto Rico, Medical Officer, Health Unit

Arthur A. Nichols, M.D., 6 Roberts St., Fargo, N. D., Acting Health Officer, Fargo

Colonel Benjamin Norris, M.D., Ashtabula County Commissioner of Health, Jefferson, Ohio

Manuel Otero-Rogue, Principal, Morovis,

Puerto Rico, Medical Officer, Sanitary Unit, U.S.P.

Edris Rice-Wray, M.D., 659 McKinley St., Apt. 6, Santurce, Puerto Rico, District Supervisor of Public Health, Arecibo, Puerto Rico

Albert H. Rohner, Hartley Dodge Memorial, Madison, N. J., Health Officer, Board of Health

David G. Schmidt, M.D., 465 Magnolia, Larkspur, Calif., Corte Madera City Health Officer

Wai Shun Sien, M.D., 2057 University Ave., Berkeley, Calif., Student, School of Public Health, Univ. of California

J. Gregg Smith, M.D., State Dept. of Public Health, Atlanta, Ga., Trainee

Clinton F. Story, M.D., D.P.H., Library Bldg., Saskatoon, Sask., Canada, Acting Medical Officer of Health, Saskatoon Health Dept.

James F. Terrell, M.D., Pima County General Hospital, Tucson, Ariz., Medical Director, Pima County Clinic

E. Burford Weeks, D.T.M., D.P.H., Box 180, Red Deer, Alberta, Canada, Medical Officer of Health, Red Deer Health Unit

Herbert B. Wise, M.D., Lewis County Health Dept., Weston, W. Va., Director, Public Health West Virginia District 4

Laboratory Section

Josefina Acosta-Matienzo, M.S., School of Tropical Medicine, San Juan, Puerto Rico, Parasitologist, U.S.P.H.S.

Alexander S. Bartha, 2526 Argyle, Chicago 25, Ill., Assoc. Bacteriologist, Health Dept., Oak Park

Sidney Bernstein, M.S., 131 Lake St., Saranac

Ruth Pearse, 125 West Forrest, Brigham, Utah, Public Health Nurse, State Health Dept.

MAKE IT A THREE-ROUND KNOCKOUT

with Dip-Pert-Tet*—
Cutter combined vaccine

Everything you want in a combined vaccine, you'll find in Dip-Pert-Tet (formerly called D-P-T):

1. Diphtheria and tetanus toxoids so purified that each cc. contains well over the standard "one human dose"...
2. Phase I pertussis organisms, grown on human blood media to maintain a vaccine of concentrated high antigenicity and low reactivity...
3. A choice of two products—Dip-Pert-Tet Plain, the unprecipitated antigens—or Dip-Pert-Tet Alhydrox, adsorbed with aluminum hydroxide.

Dip-Pert-Tet Alhydrox, in contrast to alum precipitated vaccines, maintains higher anti-toxin levels longer, and the more normal pH lessens pain on injection. Side reactions are cut to the minimum—sterile abscesses and persistent nodules are almost non-existent.

Ask your pharmacist for Dip-Pert-Tet—by name.

Supplies of Dip-Pert-Tet are still short of the overwhelming demand—but with constantly increasing production, Cutter has every hope of meeting your needs.

CUTTER

1. In the U.S. and
2. In other countries

DECEASED MEMBERS

David B. Lepper, M.D., Bluefield, W. Va., Elected Member 1923, Elected Fellow 1927, Health Officers Section.

Marshall W. Meyer, M.D., M.P.H., Madison, Wis., Elected Member 1940, Elected Fellow 1947, Health Officers Section.

D.C.Y. Moore, M.D., Manchester, Conn., Elected Member 1920, Elected Fellow 1937, Health Officers Section.

Frances Stern, Boston, Mass., Elected Member 1921, Elected Fellow 1935, Food and Nutrition Section.

Ralph E. Tarbett, Takoma Park, Md., Elected Member 1928, Elected Fellow 1930, Engineering Section.

Howard S. Allen, M.D., Woodbury, Conn.,

Elected Member 1944, Health Officers Section.

James F. Arbuckle, White Plains, N. Y., Elected Member 1946, Public Health Education Section.

Joe Davis, Seattle, Wash., Elected Member 1943, Laboratory Section.

Elsie Hickey, Toronto, Ontario, Canada, Elected Member 1944, Public Health Nursing Section.

Stroud Jordan, Ph.D., New York, N. Y., Elected Member 1944, Food and Nutrition Section.

James W. Loughlin, M.D., Newcastle, Me., Elected Member 1933, Epidemiology Section.

Albert E. Rector, M.D., Appleton, Wis., Elected Member 1943, Unaffiliated.

Holman Taylor, M.D., Fort Worth Tex., Elected Member 1930, Public Health Education Section.

Harley A. Bunner, Atlanta, Ga., Elected Member 1946, Laboratory Section.

W. W. Hume, M.D., Beckley, W. Va., Elected Member 1931, Health Officers Section

DR. CARL BUCK JOINS UNIVERSITY OF MICHIGAN FACULTY

Carl E. Buck, Dr.P.H., was appointed to the staff of the Committee on Administrative Practice, American Public Health Association, March 31, 1931. During most of the intervening years he has served as Field Director for the Association and the committee. He has now resigned from this position to become Resident Lecturer in Public Health Practice at the University of Michigan School of Public Health, Ann Arbor. His special interest will continue in the field of state and local health administration.

Dr. Buck's host of friends throughout the North American Continent will be glad to know that his unusual talents and his wealth of practical experience have been transferred to a point where his influence may be extended through his students to influence public health practice in the future. He has acquired the kind of information and experience possessed by almost no other person during the last 17 years. His mark has been made on the Committee on Ad-

ministrative Practice, on the Association, and upon local and state health services in North America.

Besides many studies and reports which Dr. Buck has made on local health agencies, both official and voluntary, there should be recorded the unprecedented series of state studies conducted by Dr. Buck during the last 11 years. Beginning with a study of Ohio in 1931, Dr. Buck's interests were extended through studies in Arizona in 1936; Massachusetts, 1936; Oklahoma, 1938; Michigan, 1939; Florida, 1939; Alaska, 1940; Louisiana, 1941; Manitoba, 1941; Illinois, 1942; Washington, 1942; Alaska (re-study), 1943; California, 1943; Oregon, 1944; Utah, 1944; Idaho, 1945; Colorado, 1946; Wyoming, 1946; Montana, 1946; North Dakota, 1947. After completing a second study of Massachusetts during the fall of 1947, Dr. Buck finished his term of service with the Association by a re-study of the California State Department of Health. Dr. Buck has announced that he will continue an interest in field work in a consulting capacity.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

(Supplemental to list in April Journal)

POSITIONS AVAILABLE

Epidemiologist for responsible state-wide program in communicable disease control requiring an experienced health officer.

Senior Bacteriologist for responsible positions in state public health Laboratories. Master's degree or experience necessary. Monthly salary \$250-\$315.

Junior Bacteriologist for positions available in state public health laboratories. Bachelor's degree with major in bacteriology or immunology required. Monthly salary \$210-265. Contact Personnel Office, Kansas State Board of Health, Topeka, Kans.

Employment Opportunities in Arizona Wanted—Medical and Other Professional Personnel in Arizona

Director of Tuberculosis Control Division, \$6,000 a year

Director of Maternal and Child Health Division, \$6,000 a year

Two Directors of Local Health Units, \$5,100 a year

Maternal and Child Health Clinician, \$5,100 a year

Clinician in the Special Field of Cancer, \$5,100 a year

Director, Hospital Survey, Planning and Construction, \$6,000 a year

Nutrition Consultant, \$3,360 a year

Dental Hygienist, \$2,400 a year

Assistant Director of Health Education, \$2,880 a year

Psychiatric Social Work Consultant, \$3,360 a year

Consulting Psychologist, \$3,360 a year

Senior Psychologist, \$2,880 a year

Junior Psychologist, 2,400 a year

Personnel Officer, \$3,000 a year

Vital Statistician, \$2,880 a year

Public health program operates under a Merit System of Personnel Administration. For further information write to: J. P. Ward, M.D., Superintendent of Public Health, Phoenix, Ariz.

Public Health Nurse wanted with Public Health Certificate. Beginning salary \$3,051 to maximum of \$3,577. Car furnished. Permanent tenure, vacation and sick leave, 5 day week. For further in-

formation apply to the Civil Service Board, City Hall, Dearborn, Mich.

Nurse for Public School System of Mount Clemens. Beginning salary \$3,200-\$3,300 depending upon training and experience. Write Box A-10. Employment Service. A.P.H.A.

Public Health Administrator. A position combining that of public health engineering and the supervision of personnel, accounting and properties in a health unit containing 57 full-time positions. The area is adjacent to the District of Columbia, has a population of 130,000, and is both rural and suburban. Salary \$4,400-\$5,060, plus a ten per cent cost of living increase. Apply to Civil Service Commissioner of Montgomery County, Rockville, Md.

Chief Health Officer for City Health Department. Department operating efficiently. Required: M.D., preferably with public health training and experience. State experience and salary expected. Apply to City Manager, Bluefield, W. Va.

City Health Officer for New England industrial city of 20,000 population; full-time position with major emphasis on child and school health program; starting salary \$6,000. Reply in detail to Board of Health, City Hall, North Adams, Mass.

Medical Director, Municipal Tuberculosis Hospital, bed capacity 115. Permanent, full time. Salary \$4,620 with full maintenance. Reply Box 583, Fall River, Mass.

Physician, as Chief of the Bureau of Tuberculosis in charge of all public health tuberculosis activities (no institutional work). Salary \$10,380 plus \$25 cost of living monthly bonus. Write to the President, Board of Health, Territory of Hawaii, Honolulu, Hawaii, by airmail.

Physician as Director City-County Health Department, Eau Claire, Wis, population 56,000; staff of 14; ideal

Reliance

on

MAPHARSEN[®] in syphilotherapy

Reliance on MAPHARSEN is reflected in its extensive clinical use—over 200,000,000 injections since 1940. The significant advantages of high therapeutic effectiveness and notable relative safety have established its value as an antispirochetal agent. Clinical and serological follow-ups continue to demonstrate its high percentage of cures. Equally adapted to intensive, intermediate or conventional prolonged treatment schedules, alone or with penicillin,

MAPHARSEN

is an arsenical of choice in the treatment of syphilis

MAPHARSEN (oxophenarsine hydrochloride, P. D. & Co.) is supplied in single dose ampoules of 0.04 Gm. and 0.08 Gm., boxes of 10, and in multiple dose ampoules of 0.6 Gm. in boxes of 10.

PARKE, DAVIS & COMPANY • DETROIT 32, MICHIGAN

SANITARY SURVEY

It seems theoretically possible to control epidemics of air-borne contagion by covering dynamic foci with threshold sanitary ventilation; these foci constitute the primary sources of contagious epidemics in the community. Any attempt to tabulate the relative importance of various atmospheres encountered in experimental studies discloses a lack of trustworthy information on the essential channels of commerce in contagion. Nevertheless, in experimental design and the interpretation of epidemiological data, the relative insignificance of unblockaded channels is tacitly assumed.

Before designing a municipal water supply, the static factors which govern spread of intestinal infection, amount of pollution (I), size of aggregation (S), and effective dilution (r), must be surveyed. Control of static factors which determine effective contact rate and exposure time is not enough to prevent contagious epidemics by sanitary ventilation; dynamic factors which determine intra-aggregational reexposure linkage of generations, and the hazard of inter-aggregational linkage of exposure within the community, i.e., the chance of introduction of infection to and dispersion from social groups, must also be evaluated. A sanitary survey of the various atmospheres breathed by aggregations under observation is required to evaluate methods of control of air-borne infection. Sanitary discrimination in

the dynamic control of air-borne contagion is even more essential than in the static control of water- or milk-borne infection.

little or no pasture available, and nearly all the feed is brought in from other places. The sources of the feed for the cows are scattered over thousands of miles. Although the chief item, hay, is trucked in from the nearby Imperial and San Joaquin Valley, grain comes from northwestern United States, soy beans from the mid-West, copra meal from the Philippines, and molasses from Hawaii.

Because of the high cost of feed and land, almost all of the cows are imported from areas where pasture is available. They are usually bought as at least 3 year old animals, or so-called "second calf heifers." Although most of them are raised in California in the San Joaquin and Sacramento Valleys, many come from Oregon, Washington, Idaho, Montana, Utah, and Colorado.

Because of the lack of pasture the cows are concentrated in pens at most dairies and the considerable manure which accumulates in the pens is removed by scraping it with a bull dozer to the center of the pen where it is loaded into trucks and hauled away to fertilizer plants.

The dairies themselves consist of pens, an open milking barn, a closed feed barn, and piles of baled hay protected on the top against rain. Although most of the population in the area is concentrated in towns of a few thousand, there are many residences quite close to the dairies, and there are occasional dairies in the towns. Over 400 dairies are to be found here, and few people can travel far from their homes without passing one or more of them.

Methods of Investigation—

Through the coöperation of local physicians the names of persons who had undergone recent febrile attacks were obtained. Cases of virus pneumonia were especially sought. These people were then visited, interviewed, and

blood samples were taken. As might have been expected in the spring, upper respiratory infection provided the principal group of illnesses to be differentiated from Q fever. This differentiation could be done in most cases by taking a history of the disease and asking specific questions about upper respiratory symptoms. The presence of sore throat, running nose, and severe cough were valuable in making a diagnosis of upper respiratory infection. The complement-fixation test was of great help in arriving at a diagnosis of Q fever.

Complement-fixation serum tests were done with the technic described by Bengtson⁴ with antigen prepared by method II⁵ from yolk sacs infected with the Italian (Henzerling) strain of *Rickettsia burneti*. Results are given as the highest dilution at which 3+ to 4+ fixation was seen. Samples of blood collected in California were shipped by air mail to the laboratory in Bethesda, Md., where the sera and clots were separated. The clots were used when indicated for attempted isolation of rickettsiae. Certain precautions were taken for shipment, stoppers were fastened down securely with adhesive tape in order that they could not be loosened by the low pressures encountered in air transport, and the mailing containers were packed tightly with cotton in order to prevent breakage.

The Diagnosis of Clinical Disease in Human Beings—

Table 1 lists the clinical cases of Q fever found by preliminary investigations. The patients seen by physicians not familiar with Q fever were ordinarily diagnosed as "virus" or "atypical" pneumonia. Pneumonitis was demonstrated when roentgenograms were done.

The diagnosis of Q fever in each case was based on a typical clinical history with confirmatory laboratory findings. The typical clinical history was the same

"Conditioned" for a **THREE-ROUND FIGHT**

Three shots of Dip-Pert-Tet*—that's all it takes to condition any young hopeful with sound immunity to diphtheria, pertussis and tetanus. Formerly called D-P-T, Cutter's combined vaccine offers these definite advantages:

1. Diphtheria and tetanus toxoids so purified that each cc. contains well over the standard "one human dose"...
2. Phase I pertussis organisms, grown on human blood media to maintain a vaccine of concentrated high antigenicity and low reactivity...
3. A choice of products — Dip-Pert-Tet Plain, the unprecipitated antigens—or Dip-Pert-Tet Alhydrox, adsorbed with aluminum hydroxide.

Dip-Pert-Tet Alhydrox, in contrast to alum precipitated vaccines, maintains higher antitoxin levels longer, and

the more normal pH lessens pain on injection. Side reactions are cut to the minimum—sterile abscesses and persistent nodules are almost nonexistent.

Ask your pharmacist for Dip-Pert-Tet—by name.

Supplies of Dip-Pert-Tet are still short of the overwhelming demand—but with constantly increasing production, Cutter has every hope of meeting your needs.

Dip-Pert-Tet Cutter

*(Combined tetanus and diphtheria toxoids with H. pertussis vaccine)

CUTTER LABORATORIES • Berkeley 1, Calif

established in yolk sacs of hens' fertile eggs by passage from guinea pigs.

Epidemiological Features of the Clinical Cases in Human Beings—

Table 1 shows that the age of the clinical cases studied varied from 15 to 62 years. Twelve males were involved, as compared to 5 females. The cases occurred from November, 1946, to May, 1947, and were still occurring in October, 1947. It seems reasonable to assume that Q fever has been occurring here for some time. As yet no seasonal incidence is apparent.

The striking feature of the epidemiology is its peculiar relationship to dairies. It can be seen that in all of the cases except two a history was obtained of having visited dairies or of having lived near them. And, as has been mentioned, it is difficult to travel far in this region without passing cow pens. Yet none of the patients had been actually employed by a dairy, and most of them had probably not come within 10 to 20 feet of a cow, so that their contact with cows was more remote than that of the dairy workers which are considered next.

Serologic Studies of Persons Not Clinically Ill With Q Fever—

We have examined sera of many persons from outside the laboratory in the past and our experience has been that

until actual cases of Q fever were encountered in epidemics, the sera were uniformly negative. The sera of patients undergoing Q fever have given clear-cut results, most patients developing antibodies to high titer during the course of their illness. However, the results on sera of persons from the milk shed area were distinctly different, as will be seen from examination of Tables 2, 3, and 4.

Acceptance for mailing at the special rate of postage provided for in Section 1103, Act of October 3, 1917.

It is doubtful whether we may attribute this improvement to the use of the confidential death certificate, since proprietary hospitals in the other boroughs of the city, which continued to use the open certificate, recorded an equal if not greater improvement. Moreover, the limited data for municipal hospitals closely approximate those for proprietary hospitals, though it should be noted that for each of these sources the recorded improvement may have been due to sampling fluctuations.

The fact that the confidential method has not proved more effective than the open appears to be confirmed by the trends in the official mortality statistics. If syphilis was completely reported, the level of the recorded death rate would be almost doubled. Even if it is assumed that only one-half of these deaths are affected by the form of certification, the rate should increase by almost 50 per cent. It is apparent from Figure 1 that the introduction of the confidential certificate in Manhattan in 1939 has had no such effect. The trend for Manhattan closely paralleled the trend for the balance of the city; it was upward until 1938-1939, and downward thereafter. Moreover, what at the time appeared to be a significant rise in the death rate in Manhattan from 1938 to 1939, now appears to have been a combination of a chance downward fluctuation in 1938 followed by one in the opposite direction in 1939. Finally, a special analysis of deaths which were reported from Manhattan in January, 1947, the ninth year in which the confidential certificate was used in that borough, reveals no evidence that the "closed" certificate has resulted in better statistics. Of 42 deaths charged to syphilis, 37 were reported from municipal or state hospitals, and 5 from voluntary or proprietary hospitals; none from persons who died "at home." Although it is possible that none of the deaths which occurred "at home"

were due to syphilis, it is more likely that some did occur but were not reported.

How then may we account for the apparent improvement in the reporting of the mortality from syphilis and the upward trend in the death rate through 1938-1939? It seems fairly certain that these phenomena resulted from the intensive educational and clinical programs to bring syphilis under control which were launched by the Department of Health in 1935. Thus, in its annual report for 1937, it was stated that "the recorded death rate from syphilis is increasing due no doubt to more accurate reporting on death certificates." The effectiveness of the campaign probably resulted in a temporary increase in the recorded death rate, followed by a sharp decline after 1939. A similar trend was recorded in Philadelphia and in other communities following their inauguration of campaigns against the venereal diseases.

Puerperal Infection (140, 142a, 145a, 147)—Numerically, puerperal infection is only a minor factor in mortality. In recent years, fewer than 100 deaths have been annually attributed to this condition in New York City. However, it is probable that the disease is significantly understated in official mortality statistics since only three-fourths (74 per cent) of the deaths from puerperal infection were so charged for the cases in this study (Tables 1 and 2). Judged by the relatively small number of cases studied, the confidential method does not appear to be effective in improving the accuracy of these statistics (Table 5).

Diabetes Mellitus (61)—Diabetes is the only major cause of death found to be underreported on death certificates. Of the 394 deaths assigned to this condition, 318, or 81 per cent, were "properly" recorded. In 54 cases, death was attributed to cardiovascular-renal diseases, and 22 deaths were

find them in countless cities, towns and rural areas throughout the United States. They are acquiring a stake in the business.

These men and women employees are part of the capitalists—hundreds of thousands of them from all walks of life—whose savings make it possible for America to have the finest telephone service in the world.

BELL TELEPHONE SYSTEM

tary hospitals were properly charged in 1939 and 1941 when the closed certificate was used. This is the same extent of agreement between hospital case histories and death certificates as was found for 1937-1938 when the open certificate was used. The mortality statistics for New York City, which are shown graphically in Figure 1, confirm this finding. Moreover, judged by the data in the second and third tiers of Table 6, diabetes was not more frequently mentioned when the statement of cause of death was made confidentially, than when it was certified on the open certificate.

Appendicitis (121)—Official statistics apparently understate the true extent of the mortality from appendicitis. Of the 406 deaths from this condition, only 344 or 85 per cent were assigned to appendicitis on the basis of the cause-of-death statements on mortality records. An additional 44 deaths were charged to diseases of the gall bladder and other parts of the digestive system, 12 to non-malignant tumors, and 6 to various other conditions. At the same time, 10 deaths apparently due to other diseases were charged to appendicitis (Table 1). Thus, only 87 per cent of the mortality from appendicitis was recorded for this group of persons who died in municipal and proprietary hospitals (Table 2).

In planning the study, it was not expected that appendicitis would be found to be significantly understated on death records. As a result, the data were not tabulated in a manner which would permit one to ascertain whether this de-

ficiency results from the omission of the condition from the death certificate or whether it is effected by the addition of other conditions which take precedence according to joint cause assignments. Judged by the data which are available for proprietary hospitals, appendicitis was more accurately charged as the primary cause of death in Manhattan during 1939 and 1941 than during 1937-1938 (Table 7). In contrast, proprietary hospitals in the other boroughs recorded appendicitis less accurately in 1939 and 1941 than in the preceding years.

It should be noted, when interpreting these data, that the changes for both Manhattan and the other boroughs are not greater than those which might occur due to sampling fluctuations. Therefore, since the trend in the recorded mortality from appendicitis for Manhattan closely paralleled that for the other boroughs of the city (Figure 1), it is improbable that the confidential method has affected the accuracy with which the condition is reported on death certificates. A probable factor is that the discrepancies arose primarily because of the lack of care with which the statements of cause of death were made on the certificates. The fact that deaths certified by internes were least accurately recorded (Table 2) appears to support this hypothesis. One should not overlook the possibility, however, that some physicians do not report appendicitis when it is the true cause of death, if its mention reflects unfavorably upon their professional ability.

Reprint prices furnished upon request

Our study of the state health department's attitudes and needs led to much the same conclusions just presented. In addition, each bureau and division in the state department felt it would like to develop educational and training programs in relation to its own service programs. This was especially true of the Division of Preventive Medical Services which includes Maternal and Child Health, Public Health Nursing, Tuberculosis, Venereal Disease, Chronic Disease, and Industrial Disease services. The Bureau of Health Education wanted consultation from us as to literature, film, and library facilities, and the Division of Local Health Services wanted to have some consultation service available to local health departments for development of local mental health programs. The administrative personnel of the state department felt they needed a group of seminars to acquaint them with knowledge about normal emotional growth and development as applied to public health practice, some discussion on the problems of personnel, and the emotional aspects of administrative practices.

A PLAN FOR ACTION

These studies enabled us to draw up a plan of action which, it was hoped, would answer some of the needs as expressed and provide us with a means to test whether our ways of teaching and educating, once they were under way, were or were not meeting the needs and thus better equipping our health workers for helping their patients handle the emotional problems of living.

In the State Health Department the program is starting with a series of seminars for the top administrators. We meet informally once a week for a planned ten or twelve times. The groups are kept small—about eighteen to twenty members. The subject matter covers the following items:

1. The essentials of emotional maturity
2. The normal growth of the personality toward emotional maturity and the defenses which handle threats to the integrity of the personality
3. The emotions of illness and convalescence
4. The doctor-patient relationship
5. The nature of authority or emotional aspects of administration

Upon completion of these seminars, other series will be held with the various specialist and consultant personnel in the state department.

In two local health departments projects are under way which represent approaches toward aiding the nurses and physicians in the clinics to grow more quickly into the role of handling the emotional aspects of everyday medical and nursing practice. The Health Department of the City of Berkeley has added to its staff a pediatrician, with training in child psychiatry, who spends three half-days a week in health department work. In one of these periods this physician sees babies and mothers in a well baby clinic. The nurses of the health department rotate through this clinic every 3 months. Another half-day is given to educational programs for nurses and school counselors, and the third half-day is used for consultation with the pediatricians conducting other child health conferences. This program has been under way so recently that no evaluation of this approach is yet in order.

I also attached myself to a local health department, that of the City of Richmond. In coöperation with the health officer and his staff, a mental health teaching program has been started. We hope it will begin to meet not only the educational needs of the nurses and physicians but also become a part of the program of a busy, well rounded, overworked health department without adding to the burdens of a staff already pressed for time. Such a program should be possible within the usually limited budget of such a health department.

"Conditioned" for a **THREE-ROUND FIGHT**

Three shots of Dip-Pert-Tet*—that's all it takes to condition any young hopeful with sound immunity to diphtheria, pertussis and tetanus. Formerly called D-P-T, Cutter's combined vaccine offers these definite advantages:

1. Diphtheria and tetanus toxoids so purified that each cc. contains well over the standard "one human dose"...
2. Phase I pertussis organisms, grown on human blood media to maintain a vaccine of concentrated high antigenicity and low reactivity...
3. A choice of products — Dip-Pert-Tet Plain, the unprecipitated antigens—or Dip-Pert-Tet Alhydrox, adsorbed with aluminum hydroxide.

Dip-Pert-Tet Alhydrox, in contrast to alum precipitated vaccines, maintains higher antitoxin levels longer, and

the more normal pH lessens pain on injection. Side reactions are cut to the minimum—sterile abscesses and persistent nodules are almost non-existent.

Ask your pharmacist for Dip-Pert-Tet—by name.

Supplies of Dip-Pert-Tet are still short of the overwhelming demand—but with constantly increasing production, Cutter has every hope of meeting your needs.

CUTTER LABORATORIES • Berkeley 1, Calif.

corporate in accordance with the pattern of our culture.

Another thing that medical workers are usually unprepared for is that parents sometimes have emotions of anger, guilt, or feelings of hostility against their children at the same time that they may have deep affection for their children. Our parents and children frequently seek for some help in understanding and accepting such feelings, and in this aspect of practice we most frequently fail to help them. To supply some of this need, which we think will also increase the health workers' understanding of emotions in adults as well as children, we are establishing what might be called a laboratory of human behavior for nurses and physicians. Here they will become a part of a nursery school staff, work closely with children, and examine their own emotional reactions to what they find in these children and parents. They will be guided in this by a staff of well trained nursery school teachers, pediatricians, and psychiatrists.

LEARNING FROM PATIENTS

Children are the best teachers in the world, if we observe and listen to them. They have constant frustrations leading to emotions of anger, sometimes hostility. They enjoy themselves simply and they normally initiate play which has much meaning for them. They form fast loyalties and are quick to detect the sensitivities and defenses in the makeup of adults. A few physicians and nurses will spend two to three months full-time, working with the nursery group under competent direction, and will be assigned one or two children whom they are to observe carefully, and try to put into writing what they observed. Under the guidance of a pediatrician, who is oriented in the emotional growth and development of children, the nurses and doctors will also spend time in the well baby, rheumatic fever, and cerebral palsy clinics, which are a part of the

hospital and the child development center. Each nurse and physician will be assigned time, at least one hour a week, to discuss with a staff member his doubts, confusions, discoveries, and feelings about what is taking place. At the same time he listens in on the parents' class and the staff discussion about the child and his family situation.

At the end of this experience it is our hope that the nurse and physician will return to the health department not experts but a better nurse and a better physician. This should come about because they will better accept themselves as agents who help people understand their feelings and problems, rather than merely telling them how to be more adequate and healthy persons. If these physicians and nurses feel such an educational experience is what they need for their own growth in their work, then we plan to expand our efforts and invite medical and nursing staff members from local health departments throughout the state to apply for this experience. These individuals, returning to their departments after such an experience, will begin to influence other local staff members and also provide a nucleus of a local staff around which inservice training programs may be started. It is our intention, once this happens, to form a small state educational team which will work through and with these workers, thus giving continual educational stimulation in the incorporation of mental health principles as part of public health practice.

What I have described to you is a beginning of an approach toward this goal. We are feeling our way along. We hope this beginning will grow into a plan that may prove practical and effective enough so that other health departments may learn from our mistakes and our successes and thus adopt it to fit the conditions and needs found in their own staffs and in their own locale.

Simple Goiter in Colombia*

HORACIO PARRA, M.D.

*Nutrition Division of the Coöperative Health Service of Colombia and
The Institute of Inter-American Affairs, United States*

SIMPLE goiter is a problem of Colombian pathology which is so prevalent and of such long existence that it has been treated by naturalists, physicians, and even writers and folklorists.

In 1808, Francisco José de Caldas, outstanding Colombian naturalist and martyr of our independence, mentioned repeatedly the problem of simple goiter in his scientific works. He apparently was the first man of learning who attributed the disease to drinking water which has an excessive quantity of lime and heavy minerals.

In 1810, Don Joaquín Camacho studied the distribution of simple goiter in Colombia. He noted the fact that in Bogotá the disease was frequent in the convents, where the source of the drinking water was a well or an artesian well—generally quite hard water. Moreover, though the efficacy of iodine had not as yet been discovered, Camacho found the lack of endemic goiter among the inhabitants of the seacoasts significant and attributed this fact to the use of sea salt.

Later in 1831, the French naturalist Boussingault observed the presence of simple goiter in human beings and animals in localities where cooking salt very low in iodine content was used. He, therefore, advised the Government of Colombia to establish the use of salt from natural iodized sources as a pre-

ventive measure against this endemic disease. So it was that, from 1831 until 1947—a lapse of 136 years—the country of Colombia has delayed in putting into practice the recommendation of this learned Frenchman.

A recent study carried out by Socarrás in 1942 on the registration of the recruits of the "Sanidad Militar" indicated that 10 per cent of the 153,000 prospective recruits were rejected from military service because of simple goiter.

On the basis of these antecedents, the Nutrition Department of the S.C.I.S.P. has carried out the following plan of study:

1. Incidence of simple goiter in Colombia
2. Distribution of the endemia
3. Propagation and extension of simple goiter
4. Causes, contributory factors, and the sequels of the disease
5. Preventive measures
6. Manufacture of artificially iodized salt
7. Financing of a project for the artificial iodization of salt and the creation and maintenance of the Instituto Nacional de Nutrición (National Nutrition Institute).

The following is a summary of these activities:

1. In order to determine the incidence of simple goiter in Colombia, the school age group was chosen among the various population classifications. The school group possesses three very necessary characteristics: first, it is representative of the general population; second, it is the most susceptible to preventive and curative treatments; and third, as a group for investigation purposes, its examination is easy and

Senate Bill Provides Aid to Medical Education

Early in May, Senator Elbert D. Thomas of Utah introduced a bill providing for federal subsidies to schools of medicine, dentistry, nursing, and public health, and for scholarships for qualified students. The bill has been referred to the Senate Committee on Labor and Public Welfare and is numbered S. 2588.

According to the *Washington Report on the Medical Sciences*, federal grants up to \$20,000,000 a year are authorized for medical schools; \$8,000,000 for dental schools; \$18,000,000 for nursing schools, and \$2,000,000 for postgraduate schools of public health. In addition, federal grants up to 50 per cent of the cost of new construction of physical facilities are authorized. To qualify for grants, schools must not impose unreasonable restrictions against admission of nonresidents or bar applicants on the basis of race, creed, color, or national origin (special provision is made for in-

stitutions in those states having racial segregation laws). State and national scholarships are provided for, the former in medicine, dentistry, nursing, and public health, and the latter in medicine alone. Holders of national medical scholarships would be pledged to serve one year in federal status for each two academic years of his scholarship. Or he would be permitted, in lieu of government obligated service, to practise in an area where a state health authority considered there to be a shortage of physicians. State scholarships include tuition and books. The other type offers, in addition, a stipend of \$90 per month. Final paragraph of S. 2588 prohibits any federal agency or officer to "exercise any control over, or prescribe any requirements with respect to, the curriculum or administration of any school, or the admission of applicants thereto."

chemical industry is to decide which products must be examined, as the toxicological facilities available today do not allow universal examination. The workers, especially those engaged in research and pilot plant activity, must be subjected to stringent industrial hygiene and medical control as this class of employee is exposed to products about which usually little is known.

In discussing the toxicology of the newer metals it is, perhaps, more accurate to use Fairhall's description and refer to them as metals which have become important industrially in recent years.² The most prominent members of this group are beryllium, cadmium, tellurium, uranium, and vanadium. There is no common group action or symptom complex. Very little is known about some of these substances, because as yet they have been used in limited amounts in restricted work or have not been recognized as having distinctive physiological properties.

Beryllium has been reported as the causative agent of two types of lung condition. One is a chemical pneumonitis which occurred in men working with fluorescent powders. Some of the beryllium salts, notably the sulfate, hydrolyze easily and extensively so that the local production of sulfuric acid in the lung could be expected after the inhalation of the dust.

Reports of a number of cases of what is termed pulmonary sarcoidosis have been appearing in the literature in the past few years. These workers were exposed to beryllium powder in the fluorescent lamp industry. The causative relationship has not been worked out and extensive laboratory investigations on this point are under way.

Cadmium has been responsible for a considerable number of fatalities due at first to a non-recognition of its physiological action but later due to a non-recognition of its presence on the parent metal. Cadmium coatings of vessels can

cause poisoning when they are used as food containers. If a cadmium-coated article is subjected to a cutting or welding torch, cadmium oxide fume poisoning may result. This takes the characteristic form of a delayed pulmonary edema similar to nitrous fume poisoning.

Cobalt is used chiefly in the production of magnets in conjunction with nickel and aluminum and as a bonding agent in metal carbide tips for the tool and die industry. Considerable physiological and pharmacological work has been performed showing that cobalt administration produces polycythemia. There have been no reports of clinical or industrial poisoning, however.

Tellurium is a metal that was found to improve the hardness and machineability of steel. Cases of tellurium poisoning have been reported due to excessive fumes. The symptoms are anorexia, lassitude, nausea, and vomiting. The main diagnostic feature is a garlicky odor of the breath and urine. These cases have not proved particularly serious.

Uranium is a poisonous element and causes kidney damage similar to other heavy metals, such as mercury. Chronic nephritis, as a result of exposure to this metal, occurred as early as 1854. There have been no reports published of any ill effects in workers engaged in purifying this material for use in the chain reacting piles.

Vanadium is a metal that has markedly increased in use as a catalyst and a component of steels. There is considerable discussion about the degree of toxicity it possesses. Pulmonary edema and pneumonitis have resulted from inhalation in animals. In workers the lung changes have been limited to an asthmatic bronchitis.

High frequency radiations, popularly called microwaves, include that range of the radio frequency spectrum from approximately 1,000 megacycles (1,000,000,000 cycles per second) to 30,000

Procaine Penicillin

has a NEW COAT...

and it's a SLICKER Coated Crystals

HYPERCILLIN* Cutter (Procaine Penicillin G in Sesame Oil) offers a suspension of 300,000 units per cc. of 120 mgm. crystalline procaine penicillin G—dispersed in fluid sesame oil with 2% aluminum monostearate.

HYPERCILLIN OFFERS

- high therapeutic blood levels for 24 hours.
- crystals coated with a free-flowing combination of sesame oil and aluminum monostearate, to minimize settling out, practically eliminate needle plugging, and delay absorption.
- optimum crystal size—large enough for prolonged adequate levels—small enough to clear 19 gauge needle.
- less injection pain, fewer reactions—preliminary reports indicate considerably less injection pain from procaine penicillin. Clinical experience has established these advantages of sesame oil:

- | | |
|------------------------------|--|
| 1. less antigenic | 3. more suitable physically and chemically as a suspending medium. |
| 2. less irritating to tissue | |

Always specify Hypercillin by name. Cutter Laboratories, Berkeley 1, California.

Training in Engineering Aspects of Atomic Energy

The Massachusetts Institute of Technology announces a school for graduate training in the engineering aspects of atomic engineering. Work will be done in the production plants of the Atomic Energy Commission operated by the Carbide and Carbon Chemicals Corporation at Oak Ridge, Tenn.

"The purpose of the school is the education of graduate students in several fields of engineering under a program which is designed to develop their ability to apply basic

principles to the solution of technical problems encountered in industry with emphasis on the engineering aspects of atomic energy."

Admission to the new school is restricted to graduate students in the several engineering departments of the Institute who have been in residence at M.I.T. at least one term and are U. S. citizens. Further information can be obtained from Professor William A. Reed, Massachusetts Institute of Technology, Boston, Mass.

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING
 AMERICAN PUBLIC HEALTH ASSOCIATION
 BOSTON, MASS., NOVEMBER 8-12, 1948

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1948, the total membership of the Association was 11,124, including 1,913 Fellows, or 17 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been of the in course a degree of Doctor of Lecture, health, Doctor of Science in Public bia Uni Doctor of Philosophy in Public \$2.00. Doctor of Medicine with at least MOTIVATION in graduate study in public health Health Educy, Master of Public Health, Di-York Academy, or other equivalent

degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Appli-

NO MESS...

NO GREASE...

NO SCABIES

You remember how just hearing that a certain patient had scabies or pediculosis would make you itch even if you never went near him. And you remember only too well the ointment-smeared bedding that seemed the only way to get rid of the pesky skin parasites.

Now all this is obsolete. With 'Wellcome' Benzyl Benzoate Emulsion, the patient is merely painted with a clean, *non-greasy* emulsion, and when he bathes twenty-four hours later, the parasites are dead. Recurrence and dermatitis are infrequent.

— 'WELLCOME' BRAND —
BENZYL BENZOATE
 — EMULSION 50% —

Diluted with an equal volume of water before application. 2 or 3 fluid ounces of the 25% emulsion is usually sufficient for one treatment.

BOTTLES OF 4 FL. OZ.
 BOTTLES OF ½ GALLON

Literature upon request

WELLCOME & CO. (U.S.A.) INC., 9 & 11 EAST 41st ST., NEW YORK 17
 Please write to Advertisers say you saw it in the JOURNAL

Journal (p. 1049). At that time the first issue of the Dermatology and Venereology Section had been published. Now Vol. 1, No. 1, of Section IV on Medical Microbiology and Hygiene, has appeared, in January, 1948. Among its American board of editors are Drs. Charles Armstrong, Martin Frobisher, Jr., Hugh R. Leavell, Ernest L. Stebbins, and C.-E. A. Winslow. The material in this section is divided into three main classifications: Medical Microbiology, Hygiene and Public Health, and Medical Entomology and Medical Parasitology.

At the same time the first issue of Section XV on Tuberculosis appeared. Among its editors is J. Burns Amberston, M.D.

All but one of the fifteen sections have now begun publication.

ANOTHER MEDAL FOR DR. CORI

Dr. Carl F. Cori, a Nobel Prize winner and winner of a 1946 Lasker Award of the American Public Health Association, recently received the 1948 Willard Gibbs Medal of the Chicago Section of the American Chemical Society for his achievements in research on processes by which the human body converts sugar into energy. Dr. Cori is Professor of Biochemistry in the Washington University School of Medicine, St. Louis, Mo.

COMMITTEE TO STUDY FEDERAL GOVERNMENT'S MEDICAL AND HOSPITAL FACILITIES

The Commission on the Organization of the Executive Branch of the Government, which is headed by Herbert Hoover, has announced the following members of a committee which will investigate the government's medical and hospital services:

Tracy S. Voorhees, president of Long Island College Hospital, Brooklyn, N.Y., chairman; Drs. R. C. Buerki and O. H. P. Pepper (University of Pennsylvania),

Hugh J. Morgan (Vanderbilt), Allen O. Whipple (Columbia), W. C. Menninger (Menninger Foundation), Ray Lyman Wilbur (Stanford), Frank R. Bradley (Barnes Hospital, St. Louis), Michael DeBaKey (Tulane). Also on the committee are Charles F. Rowley, former trustee of Massachusetts Investors Trust; Henry Isham, president of Chicago's Passavant Hospital; Dr. Paul R. Hawley, Chief Executive Officer of the National Organization of Blue Cross Hospital Service Plans and Blue Shield Medical Service Plans; and Rear Admiral Joel T. Boone, secretary of the special board now investigating armed forces medical and hospital services.

MORE BABIES AND THEY LIVE LONGER

The National Office of Vital Statistics recently announced a new low infant mortality record for the United States in 1947 of 32.6. The number of live births registered also set a new high record of 3,720,000. The provisional general death rate for the country was 10 as compared with the lowest recorded, 9.9 in 1946.

CHANGES IN STAFF ASSIGNMENTS, U. S. PUBLIC HEALTH SERVICE

Several changes have taken place in the staff of the U. S. Public Health Service in Washington following the assumption by Dr. Leonard A. Scheele of his duties as Surgeon General.

The Federal Security Administrator has nominated for the rank of Major General, Drs. C. L. Williams, Sr., Chief of the Bureau of State Services, and R. C. Williams, Chief of the Bureau of Medical Services. Also nominated for the same rank was Dr. Rollo E. Dyer, Director of the National Institute of Health.

Dr. John R. Heller, who has served as Chief of the Division of Venereal Diseases since 1943, has been appointed Director of the National Cancer Institute, Bethesda, succeeding to the post

appointed anesthesiologist of the Department of Obstetrics of Johns Hopkins, Baltimore, effective July 1. He will be on special assignment from the U. S. Public Health Service to conduct a 5 year program in the relief of pain in childbirth.

CLARENCE I. STERLING† has been named Director of the Health and Sanitation Division, Institute of Inter-American Affairs, Washington, D. C., to succeed RICHARD J. PLUNKETT,† who resigned to become Assistant Editor of the *Journal of the American Medical Association*.

E. J. SUNKES, DR.P.H.,* has been appointed Director of the Division of Laboratories of the State Department of Public Health, Atlanta, Ga., succeeding THOMAS F. SELLERS, M.D.,* who was recently appointed Director of the State Department of Health. Dr. Sunkes has served 26 years with the Georgia State Laboratories.

NORMAN H. TOPPING, M.D., with the U. S. Public Health Service, Washington, D. C., has been appointed to the new position of Associate Director of the National Institute of Health, Bethesda, Md.

JESSE MEUSE was recently appointed as Negro Health Educator for the Florida State Board of Health, Jacksonville. He has had many years of experience in the field of public health and teaching in public schools of Florida. As a member of the division of health information, he will work with various groups in the promotion of better health among the Negro population of the state.

JOHN MULRENNAN, Director of Entomology, Florida State Board of Health, Jacksonville, was named President of the Florida Anti-Mosquito Association, at a joint meeting of the Florida group and the American Mosquito Association, in Ft. Pierce, Fla., March 18-31.

Western States

HAROLD D. CHOPE, M.D.,* Assistant Health Officer of the San Joaquin public health district, and a former Assistant Director of the California State Department of Health, became San Mateo County, California, Health Director, as of May 1.

CHESTER A. FEE has joined the staff of the Oregon State Board of Health, Portland, as Health Information Consultant. A veteran of World War I, Mr. Fee worked as an educator in California for some years. He has been associated with newspapers and magazines as writer or editor. Formerly with the Department of English at the University of Oregon, he is best known as the author of *Chief Joseph* and other works.

Other Areas

JOSEPH N. LANOIX† has been appointed Director General of Hydraulic Services for the Government of Haiti and for the American Sanitary Mission in Haiti.

SAM H. ZIA, M.D.,† of Peiping, China, has been appointed Professor and Head of the Department of Bacteriology of the Peiping Union Medical College, effective April 1. Dr. Zia is known in the United States as a former associate of HANS ZINSSER, M.D.

Deaths

EDNA M. KECH,* Director, Division of Health Education, State Health Department in Pennsylvania with offices in Harrisburg, died recently in Florida.

CONRAD KINYOUN,* Director of the Department of Health Laboratories of Savannah, Ga., died March 31. Burial was in the National Cemetery, Arlington, Va., with full military honors.

Simplicity

in Dextrose Administration

No involved procedures with Cutter Solutions in Saftiflasks!
From meticulously tested solutions—to ready-to-use, disposable
injection equipment—the Saftiflask set-up is designed for
simple, trouble-free administration in your hospital.

Sterile, pyrogen free solution is removed from stock and inspected for clarity.

Disposable intravenous set, already assembled and sterilized, saves time for nurses and other technicians.

Attending physician makes a final examination, to be certain solution checks with his written orders.

FIGURE 5—Relative densities of malaria-carrying species of mosquitoes within and adjacent to protected zones in the United States during the five World War II years.

were developed to teach the lay public simple facts about the cause, nature, transmission, and prevention of malaria, thus securing cooperation in effecting the objectives of the program.

The main malariologic shortcoming of this War Areas Program was that it was aimed only at the protection of military trainees and war workers. Thus it did not nullify foci of primary malaria endemicity unless they were near military training camps, maneuver areas, airports, shipyards, or the sites of war industrial or recreational facilities.

A third federally sponsored program which may have exercised some effect on anopheline prevalence over a considerable portion of the South is that of the Tennessee Valley Authority. This organization was created in 1933. Since then it has constructed or acquired 26 artificial impoundments along the Tennessee River and its tributaries. At maximum normal operating level, these lakes cover nearly 600,000 acres, and their total shore line extends well over

10,000 miles.²⁶ Much of the marginal area is within the limits of traditional malariousness where conditions favor the propagation of *A. quadrimaculatus*, a notorious impoundment breeder. The threat of enhanced malaria incidence was recognized early in the planning phase and, as an important element of the Health and Safety Department, a Malaria Control Division was activated. Its functions, at first investigational and operational, now consist of the development of the TVA malaria control program and the planning and appraisal of its execution in the field. The anti-larval measures utilized include reservoir preparation and improvement, water level management, larviciding, drift removal, and herbiciding—all prosecuted on very large scales. The studies of the TVA Malaria Control Division and the operations performed by it or under its technical supervision appear to have not only kept malaria from becoming a major cause of morbidity in the Tennessee Valley but have reduced to the

SUMMARY

1. Data from death certificates were studied for indications of medical attendance during terminal illness.

2. The certificates which were used constituted approximately 10 per cent of the recorded deaths which occurred in seven states selected as illustrative of all states. The deaths due to external causes, if death occurred within 24 hours, were excluded from the analysis.

3. The data on place of death (i.e., hospital or home) and on attendance as recorded by the certifying physician (last attendance before death; length of attendance) were considered to be indicative of medical attendance during terminal illness. They were tabulated in relation to such factors as size of community in which death occurred, age, and race.

4. Nearly 10 per cent of all deaths (exclusive of those due to accident and violence with death following "imme-

diately") were classified as "without any attendance."

5. Some correlations were found between size of community in which death occurred and adequacy of medical attendance. As in the case of hospital deaths, home deaths with routine attendance were more frequent in the larger population size communities, but home deaths without any attendance seem also to have been relatively more frequent in large cities. Deaths without recent attendance were relatively most frequent in rural areas.

6. Lack of any medical attendance among persons dying at home was found to be particularly frequent among the very young and the very old in states where "unattended deaths" were relatively numerous, and among Negroes.

7. Nearly 62 per cent of the cancer deaths occurred at home; the proportion of home deaths increased with increasing age. Four-fifths of all cancer deaths were classified as having routine attendance.

Course in Application of Nuclear Physics to Biology and Medicine

The University of California at Los Angeles announces a summer course in the Application of Nuclear Physics to the Biological and Medical Sciences, August 2-20 under the direction of Fred Bryan, M.D., Associate Clinical Professor of Medicine, School of Medicine, University of California at Los Angeles, to whom application should be made.

The program for the 3 week course includes one or two lectures and a daily afternoon laboratory session of 4 hours. The lectures are scheduled once a week. The teaching staff includes 20 members of

whom 16 are University of California Professors. Others include Enrico Fermi, Ph.D., of the University of Chicago, Gerhard Dessauer, Ph.D., Research Chemist of General Electric Company, and George M. Lyon, M.D., Chief of the Radioisotope Section of the Research and Education Service, U. S. Veterans' Administration.

Enrollment in the course is limited. Applicants must present biographical data for approval by an official committee. Tuition fee for the complete course is \$350, for the lecture series alone, \$100.

TO THE EDITOR:

The official administrator is becoming aware of the effect upon family life of having a number of social workers entering the home, and there is a growing danger of resentment of this too frequent intrusion on privacy. As it is, one should expect that only one of the several workers will really gain the confidence of the family. Who is that worker to be to whom the family can look for counsel and advice?

The public health nurse was followed by medical and psychiatric social workers, case workers, and now mental hygiene is recommending another field worker. It is probable that, had the educators of public health nurses placed less emphasis on nursing, it would have been possible to have extended the scope of the responsibility of the public health nurse to these other social fields. Analysis has shown that the actual nursing care undertaken by the health nurse averages only about 35 per cent of her time. In spite of this, in addition to the requirement of a nursing certificate, there is much reiteration of techniques and procedures already taught in the nursing school during her training for public health. Hours are wasted on demonstrations of "how to bathe a baby, how to clean a thermometer, how to give a bed bath," etc. These unimportant details rob the health nurse of the joy of using her initiative and of accomplishment from her own decisions of what to do and what not to do in a given situation.

The writer feels that the time is overdue for review of the problem implied above. A job analysis should be made

of the health care needs of the family, not only physically but also mentally and socially, to determine the type of training to prepare a single professional worker to meet these needs. In fact, the term "public health nurse" no longer describes her functions, and confuses the public as to the scope even of her present activities. This combined individual might be designated the "health care worker" to be the "spearhead" of health care activities, as expressed by Dr. Parran. Schools of public health should be responsible at a professional level for establishing a department to train this worker. In the field she should be assisted by trained practical workers in much the same manner that the movement is growing for professional hospital nurses to devolve many of their nontechnical duties on the practical nurse. In turn, the Health Worker would be supervised by individuals who had taken postgraduate training in the various phases of the field such as mental, social, etc. The undergraduate training of this Worker could very well be set up in terms of the job analysis report to include certain of the fields now required in the undergraduate training of social workers and nurses.

It is greatly to be hoped that the current School Study of the National Nursing Council will give priority to the rapidly growing problem outlined above.

ANNE H. McCABE, *Director*
Division of Public Health Nursing,
Department of Health,
County of Westchester
White Plains, N. Y.

Dec. 3, 1947

staff or with the staff of the entire health department

B. In the community

1. Individual, such as with executive secretaries of voluntary health agencies
2. Group, such as with teachers and school administrators

II. Observation

- A. Activities of the health department, such as child health conferences, immunization clinics, laboratory procedures, record keeping, and field visits of nurses and sanitarians
- B. Activities in the community, such as meetings of community health councils
- C. Resource materials in the health department, such as literature, audio-visual aids, and demonstration materials
- D. Resource materials in the community, such as literature, audio-visual aids, and demonstration materials

III. Participation

A. In health department activities

1. Routine activities, such as talking on the school health program at a staff meeting of the entire department, inspecting restaurants under the supervision of the sanitarian, and assisting the nurses at a child health conference
2. Special activities, such as planning in detail with all professions in the health department specific procedures for the coming year's school health program

B. In community activities

1. Special activities, such as speaking on plans for the school health program before a council of social agencies and calling a meeting during the summer of school administrators and teachers on the school health program

following values were among those resulting:

A. Joint values

1. The whole school-community cooperative program will benefit due to the closer relationships established between the coordinator, the health department, and the voluntary health agencies in the community.
2. One of the biggest values obtained is the great amount of joint planning now taking place for the school-community cooperative health program in those areas where the project operated.
3. Opportunity was provided to work out harmoniously the answers to certain unsolved problems which had been the cause of irritation and friction in the past.
4. Through joint conferences, the coordinator and health department staff decided upon specific problems with which they needed help. These difficulties were straightened out at the intensive short course in health education at the university.

B. Values to the school

1. Through this project the entire school health program was related more adequately to that of the community.
2. The coordinators became better acquainted with the health department's philosophy, program, and personnel.
3. Teachers were made more aware of the home and community aspects of the school health program.
4. The specific functions of the coordinators were established more clearly, especially as they concern relations with the health department and other community agencies.
5. The coordinator became acquainted with both resource personnel and material which she and other teachers will use in the health instruction program.
6. Health teaching was made more functional through field trips and student participation in community activities growing out of the contacts established by the coordinator during the project.
7. The values of school health councils were brought home to the extent that several new ones are being planned.
8. In one area the coordinator and nurse have become a team which has demonstrated a successful teacher-nurse con-

Values of the Project

There is no doubt that this project has measurably benefited the school-community health program in those areas of the state in which it operated. In addition to those intangible gains such as broader viewpoints, improved attitudes, and greater cooperation, the

Clearing House on Public Health Salary Information

Salary Study of the Vital Statistics Section

AT the 75th Annual Meeting of the Association, Dr. Paul M. Densen, Chairman of the Vital Statistics Section's Committee on Professional Standards and Remuneration presented an interim report to the Section. He has prepared a summary of his interim report for the Clearing House, even though the final report has not yet been prepared.

The Committee on Standards and Remuneration was originally charged with the responsibility of obtaining up-to-date information on the salaries of professional personnel engaged in the field of public health and vital statistics. Since then the Section has also appointed a Committee on Opportunities in Statistical Work under the Chairmanship of Ellen W. Jones and the Association's Committee on Professional Education has appointed Dr. W. Thurber Fales as Chairman of its Subcommittee on Education Qualifications of Personnel in Vital Statistics and Vital Records. At a meeting of the chairmen of these three committees in April, 1947, the Committee on Standards and Remuneration was asked to enlarge the scope of its inquiry to include consideration of the educational background of persons in the field, of the manner in which they first learned about statistics in general and public health or vital statistics in particular, and of the number of existing vacancies.

In order to present as complete a picture as possible, the committee decided not to limit its efforts to state departments of health but to get information on salaries in the federal government, in various foundations and societies concerned with public health

matters, and in schools of medicine and of public health.

It was then found that the Division of Public Health Methods of the U. S. Public Health Service was planning a study of salary scales to be done chiefly by staff visits to a good many states and cities to study the statistical organization. An agreement was therefore reached with the Service to have its staff member Mr. Swinney take our committee's questionnaire to the departments in his itinerary. This would yield information more quickly than a mailed questionnaire and would also tend to insure the reliability of the data through interpretation of the questions by one individual. Since the states visited by Mr. Swinney have the most extensive statistical organizations, it is felt that the information on the majority of statistical personnel in state health departments is fairly representative.

The first question the committee faced was what sort of personnel should be included in its survey. It wished to include personnel in "statistical positions" only but recognized that "statistical position" is exceedingly difficult to define.

In the states visited by Mr. Swinney the working definition used included:

1. All personnel classified as statisticians
2. All personnel doing work of an analytical nature demanding some knowledge of statistical principles and methodology
3. All personnel doing professional registration work (i.e., persons who worked on policy levels and who might be considered as potential registrars)
4. Other personnel reported as doing statistical work.

The instructions for filling out the questionnaires sent to the states not vis-

Environmental Health Problems Related to Urban Decentralization*

As Observed in a Typical Metropolitan Community

LEONARD M. BOARD, M.P.H., F.A.P.H.A., AND
HERBERT J. DUNSMORE, M.P.H., F.A.P.H.A.

*Senior Assistant Sanitary Engineer, U. S. Public Health Service, Ann Arbor, Mich.;
and Director, Division of Sanitation, Calhoun County Health Department,
Battle Creek, Mich.*

THE decentralization trend of population from central cities to fringe areas presents a growth pattern encountered in the majority of American cities, small and large, and is a reversal of the trend responsible for the growth of our cities. Planners and municipal authorities have emphasized the gravity of the shrinking tax base of the core city, the economic obstacles to adequate servicing of satellite developments with schools, fire and police protection, water, sewers, refuse collection, the need for effective controls of suburban areas, and other readily apparent difficulties accompanying the changing growth tendency. Students of local government, including leaders in public health administration, have been advocating consolidation of many functions and services, a measure which suggests the urgency for state and local public health engineers to contemplate the environmental health problems and needs in suburban areas.

A reconnaissance study of a fairly typical metropolitan community was conducted by the authors, as a portion of a comprehensive planning project. The

authors' participation was limited to environmental health factors of public health significance, including some which were the responsibility of agencies other than the health department, in an effort to indicate the public health engineering functions and responsibilities as they relate to metropolitan community planning and administration.†

The community in question includes a central city with a 1940 population of 150,000 and a density of 1,900 per sq. mi. The four surrounding townships contained in the U. S. Census Metropolitan District had a 1940 population of approximately 40,000. However, the density in census tracts adjacent to the city varied from 40 to 1,800 per sq. mi. Figure 1 depicts the relative growth of the city, the contiguous townships, and the county. Neither townships nor census tracts were utilized to delimit the metropolitan area for the purpose of this study, since it was directed primarily at the existing community rather than the anticipated ultimate growth. The criteria applied included population density, as measured by lot size and frontage, topography, platted subdivi-

* Presented before a Joint Session of the Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

† Several environmental health factors were not included in this study because of time limitations and their poorly defined relationship to the decentralization movement, i.e., rodent control, atmospheric pollution.

ited by Mr. Swinney were to include all positions to which any statistical work was attached, either of an analytical or clerical nature. It was thought that this would insure that no positions which should be included would be omitted and that, from the job descriptions, persons fitting in the groupings used by Mr. Swinney could be selected.

It was decided to have the questionnaire filled out by the worker rather than by the organization since much of the information desired would be best known to the individual. The worker was asked to describe his duties in his own words since it was thought that this might afford a better description of his job for the committee's purposes than the merit system classification description.

Data on vacancies and plans for expansion were secured by means of an organization schedule for states not visited by Mr. Swinney. For those that were visited, the information was made available from data collected by Mr. Swinney. In addition, material already present in the files of the Division of Public Health Methods and of the National Office of Vital Statistics was utilized.

RESULTS

The findings here presented are limited to the 23 states visited by Mr. Swinney and to broad categories rather than detailed breakdowns. These preliminary data are heavily weighted by the returns from a few states with large statistical organizations. The data are presented here more to illustrate the nature of the analysis than for their own sake. Interpretation of the data must await more detailed analysis of the complete returns.

The first problem faced by the committee in the analysis of returns was to develop a classification of the various statistical positions. The multiplicity of job titles made it impossible to use

these as a basis for classification. It was deemed unwise to force the returns into a theoretical classification. Instead, an attempt was made to develop a classification based upon the job descriptions given in the questionnaires. Accordingly the job descriptions were carefully studied *without regard to salary or title of job* and those questionnaires whose job descriptions were judged to be similar were placed together in one group. (Although this yielded several seemingly distinct groups, it should be recognized that the scale of classification is actually a continuous one ranging from individuals just above the clerical level with very little independence of action to chiefs of division responsible for policy.) The classification resulted in two main groupings, chiefs of bureaus or divisions (represented by Groups I, II, and III) and various levels of subordinate personnel (Classes A, B, C, D). Each of these is described below: *

Group I (Chief Statistician)—Workers in this category are chiefs of a statistical unit engaged primarily in analytical work exclusive of registration activity. In coördination with other activities of the health department they are responsible for the development of a statistical program from the planning stages through the final analysis and presentation of results. They exercise considerable independence of action within the broad policies laid down by the health commissioner.

Group II (Registrar)—Chiefs of a statistical unit engaged primarily in the registration of births and deaths. Responsible for formulation of policy in relation to registration matters and at times for analysis of the registration function but not engaged in analysis with regard to health department activities as a whole.

* For ease of reference a descriptive term is placed in parentheses after each classification. The use of letters to designate the classes is not intended to represent a decreasing order but to emphasize that there is a similarity of functions irrespective of title.

parity between city and district water costs to the consumers.

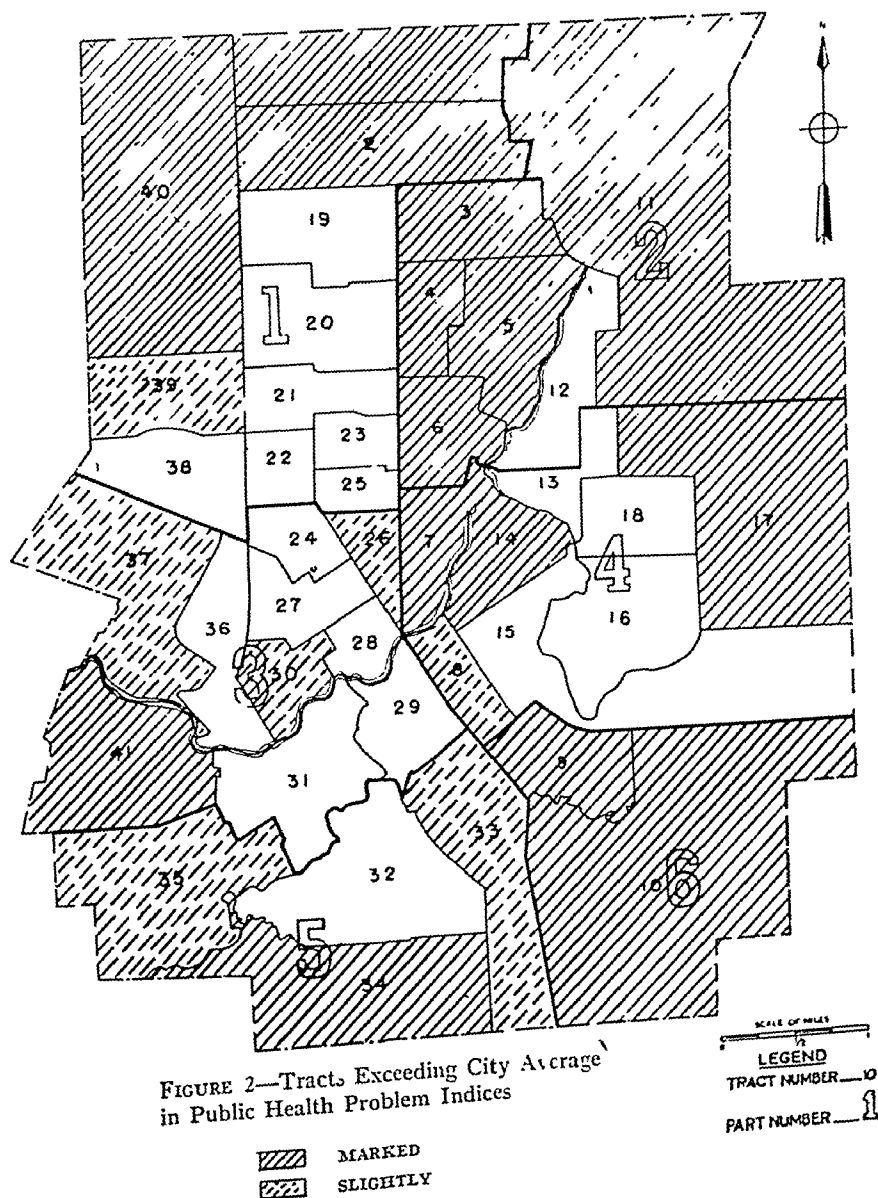

e. County health department supervision of the district supplies is limited to periodic sampling, despite the fact that they are operated by untrained men. A considerable number of private wells dried up when the district wells were drilled, creating a pollution threat to the district wells and other private supplies, but no program for sealing of dry wells has been undertaken.

f. More than 12,000 persons in the

area studied depend on private wells, many located on small lots which also function as sewage disposal sites.

Sewerage—

a. Over 90 per cent of the city's population live on sewered streets, but 2,600 privies and a like number of septic tanks and cesspools are in use. The large proportion of "temporary" and substandard dwellings constructed during former periods of rapid expansion poses a difficult obstacle to enforcement

Group III (Chief Statistician and Registrar)—Chiefs of a combined registration and analysis unit. These combine the duties and exercise the responsibilities of the Chiefs in Groups I and II.

Class A (Assistant Registrar)—Individuals in this group usually function under the immediate supervision of someone in Group II. They ordinarily engage in no analysis but are given considerable responsibility for the routine production of vital statistics and may be directly in charge of a large clerical office. When necessary they may act in the place of the person in charge of the registration unit.

Class B (Senior Statistician)—Under the general supervision of individuals in Group I or Group III they are responsible for analysis of a high order of technical competence demanding a good general knowledge of public health. May consult with chiefs and other personnel of the health department with regard to planning of a study, collection of data, tabulation and analysis of results. Under general supervision only, may initiate studies and exercise considerable independence of action within broad policy lines laid down by the chief. Analytical work not confined to one particular aspect of public health.

Class C (Junior Statistician)—Individuals in this class are usually under the immediate and fairly close supervision of individuals in Class B. They do not confer, except on rare occasions, with chiefs of other divisions. They may supervise a small clerical or tabulating force or be responsible for some tabulating work.

Class D (Statistical Aide)—Workers in this class are responsible for the routine computation of rates and ratios and the construction of graphs and tables under the immediate supervision of someone in Class B or C. They may supervise the production of routine statistical reports and the abstracting of

indicated by an estimated 20,000 vacant subdivided lots in a mile-wide belt surrounding the city in 1938. The rate of home construction in the four townships surrounding the city has been greater than inside the city since 1930. Of the total number of dwelling units existing in the respective areas in 1940, 47 per cent were built in the townships since 1930, as compared with 10.5 per cent of the city total.

e. Some indication of suburban housing quality may be observed in these 1940 census figures for tracts bordering the city: From 0.1 to 25.7 per cent needing major repairs; 10.0 to 17.1 per cent with no running water; 13.5 to 30.7 per cent with no inside flush toilet.

County health department records reveal the construction of 446 septic tanks in the 4 suburban townships in 1946.

Overcrowding in 1940 existed in the unincorporated fringe in a ratio three times that of the city, a substandard condition not attributable to the lack of public water supply and sewers.

The ratio of home ownership in the unincorporated section is significantly higher than in the city, but the rate of turnover is much higher outside the city—a factor which may explain the want of concerted effort to secure community improvements.

Miscellaneous—

The scope of this study did not permit the examination of such environmental facilities as parks, swimming places, play areas, schools, drainage works, dumps, and various others. However, it was pointed out that the suburban sectors were deficient in the provision of public recreational facilities and depended largely on city and state services.

SERVICES RELATED TO ENVIRONMENTAL HEALTH

Garbage and Rubbish—

a. Collection practices in the city were evidently adequate, but costs were

obviously affected by the extensive outlying developments with houses widely scattered.

b. No public collection service was available for the suburban metropolitan area. Independent collectors were subject to no control. Vacant lots and roadside ditches have become unsupervised refuse dumps, as might be expected.

Food and Milk Control—

The city program has been an outstanding success, noted particularly for its pioneering efforts in educational techniques. But adjacent unincorporated areas, although similarly urban in character were governed by state statutes and regulations enforced by the State Department of Agriculture. Fortunately, amicable relations established with the agriculture department permitted supplementary inspection by the county health department, but legal requirements for the contiguous communities contained many disparities, such as the lack of any meat inspection requirement for unincorporated communities.

Miscellaneous Health Department Services—

a. Among the other services rendered more difficult by the decentralization movements have been the control of nuisances, house trailers, unkempt vacant lots, various types of business establishments, and the like. Former city residents, accustomed to expect high standards of service, fail to comprehend the limitations they encounter when they move outside the city into a newer and apparently more desirable subdivision.

SERVICES AFFECTING ENVIRONMENTAL HEALTH BUT ADMINISTERED BY AGENCIES OTHER THAN THE HEALTH DEPARTMENT

a. Planning, zoning, subdivision controls, and related services bear forcibly upon the community environment.

multiplicity of existing job titles, which are shown in Table 2 for the same group of workers.

It is the purpose of this report to explain how the data for the committee's study are being collected and to indicate the general method of analysis. This report will then serve as a background for further reports of the committee in which it is planned to present detailed tables of the findings. No interpretation of the material is attempted at the present time since it is heavily weighted by the returns of a few states with large statistical units, the effect of which cannot be determined until all

reports are in. The committee also desires to make certain cross-tabulations of the data before attempting an interpretation. When all of the data have been collected it is hoped to compare the salary picture of persons doing statistical work with that of workers with equal responsibility in other fields of public health. Comparisons of federal, state, and local salary scales and of salaries paid by schools of public health and foundations may also be made.

In addition, information at present available to the committee on existing vacancies in state health departments is shown in Table 4. It should not be

* Plus cost of living adjustment

and isolation, it is extremely difficult to obtain or to hold, essential trained health personnel.

There is no doubt at all of the accuracy of this diagnosis by the Medical Mission. Those of us who have been familiar with the situation realize, however, that a sound basis for progress has been laid in the past three years. Under the able and courageous leadership of Governor Ernest Gruening, a Territorial Department of Health, with a full-time Commissioner (Dr. C. Earl Albrecht) was established in 1945. This department secured from the Territorial Legislature an increase, from \$30,000 to \$250,000, of the funds locally appropriated for control of tuberculosis. It obtained the two tuberculosis sanatoria, to which reference has been made, and initiated a comprehensive case finding program. It operates two mobile units, one on a truck for inland areas and one on a Health Boat for the coastal villages, and a third unit in an aeroplane is projected for the more remote villages. The Medical Mission rightly points out that the extensive use of BCG immunization would be highly desirable in such an area as this. Twenty-one generalized field nurses work in the territory under two supervisors. Sanitation and laboratory services have been notably strengthened; and a nutrition consultant has been appointed on the department staff. Particularly notable is the establishment of a Health Education Unit, which has done excellent work. Health councils in various parts of the territory were influential in supporting the work of the department.

The Territory of Alaska has sound and potentially effective machinery for dealing with its problems. The financial resources to carry out its program must come largely from the federal government. Action taken by the present Congress seems likely to be of material assistance; but what has so far been done is only a beginning. The Medical Mission is on sound ground when it says: "For those who decry federal aid, the committee wishes to point out that the problem in Alaska has existed for many, many years without even an effort toward a solution until 1945. The territorial funds are insufficient to meet the present needs of Alaska in tuberculosis control. Alaska has been a neglected possession of the United States up to recent years. The war years and its present eminence on the 'left flank of the North American Continent' have brought Alaska into the national conscience. The citizens of Alaska, its officials and the health authorities are cognizant of the acute problems. Defense of Alaska would best be accomplished with a healthy populace."

Turning to Puerto Rico, we find, again, serious health problems although by no means so grave as those of Alaska. The underlying causes of these problems are, in many respects, precisely opposite in the two areas. Alaska is Arctic, Puerto Rico, in the Tropics. Alaska is underpopulated, with nearly six square miles per person. Puerto Rico is overpopulated, 620 persons per square mile (over two million people in 3,435 square miles). This is the approximate density of Rhode Island; and for a primarily agricultural community represents desperate overcrowding. The situation becomes worse every year, since the birth rate of over 40 per 1,000 produces a net increase of population of about 65,000 per year.

The Medical Mission limited itself here, more narrowly than in Alaska, to the problem of medical care.² Hospitals in Puerto Rico are of three types, District, Municipal, and Private. The District Hospitals (now five in number) are operated by the Insular Department of Health (J. A. Pons, Commissioner). They have been greatly improved in recent years and the Mission reports that "they are a credit to those charged with medical care in the island." The municipi-

thought that these vacancies represent the potential demand for statistical personnel. Rather they represent positions which, as far as is known, can be filled immediately. A better idea of the po-

tential demand is the fact that 25 of 41 states replying reported plans for expansion in statistical work. This phase of the problem will be further developed in subsequent reports.

Health Officer for a Day

as told by BILL SILER to CHARLES B. FRASHER *

THAT was an exciting day in my life when I took over the duties of the Commissioner of Health for Oklahoma. You want me to tell you about it? Well, hang on and here goes. I hope you will excuse me for having been so ignorant about what the Health Department does but I just never had any realization that the programs of public health were going on in my state. I guess I have been too interested in the things immediately around me to observe how the government was being run. Of course I'm interested in the United Nations and aspects of international or national government. But local government has passed me by.

How did I get the opportunity of acting as Commissioner of Health? Well, yearly, in connection with Father and Son week, each of the six high schools is given the opportunity of electing a number of seniors to take over state, local, and school jobs for a day. Our school was assigned ten positions and I was elected to be the Commissioner of Health.

What did I know about public health before I went out to the Health Department? You'll laugh at this, but it's true. I didn't even know where the Department of Health was. Oh, I knew the old building which used to be an old soldier's home or something, was the place where you got a birth certificate. And I knew the Health Department was responsible for checking restaurants and swimming pools and making them clean. My Dad had discussed this with me when our gang wanted to arrange a supper party at a little local restaurant. Oh, and yes, I knew they had a V.D. program because you can see the signs in the busses and on the public trash cans. But I guess that's all I knew beforehand. It really was an eye-opener, that day as Commissioner. I wish I could tell all the high school kids about it.

What did I learn the day I was Commissioner? Well, that's a big order. It was so educational I couldn't take it half in. I spent the morning with Dr. Mathews, the real Commissioner, you know. And say, do you know he is the first state health commissioner to stay in office more than four years in our state. That isn't right, you know: you won't find many people as smart as Dr. Mathews is and he ought to be kept at his job regardless of who the governor is. It is more economical I guess and

* Mr. Frasher, Field Consultant in the Merit System Unit of the American Public Health Association was visiting Oklahoma when Oklahoma City was celebrating Father and Son week. He met William Howard Siler, a 17 year old senior at Classen High School who was acting as the Commissioner of Health for a day. The remarks in this article are taken as closely as possible from an interview with Bill Siler and are presented for the interest of public health workers.

ranges have been eliminated in this edition. This material will be missed by the younger college or high school student who knows little about the work. However, a choice has to be made as to length of a pamphlet. A long pamphlet may not be read, a short one has to cut corners.

Many of the universities which offer appropriate training are named and references for further information are shown.

With an authoritative and attractive document available, the job ahead is a discriminating distribution where it will do the most good. Vocational counselors, in particular, at all school levels should have this booklet at hand.

GEORGE T. PALMER

Experimental Air-Borne Infection
—By Theodor Rosebury, Baltimore:
Williams & Wilkins, 1947. 222 pp.
Price, \$4.00.

This monograph presents the results of a study of experimental air-borne infection, a cooperative wartime project at Camp Detrick, Maryland, from December, 1943, to October, 1945. Demonstration of the infectiousness of air when contaminated with bacteria and viruses has been shown by others, but the author rightly points out that all cloud chamber methods employed prior to this study would be hazardous to the personnel should highly virulent agents be used. This investigation, therefore, is of special importance because its main purpose was to "devise and set up an installation equipped for the study of air-borne clouds of highly infective agents under conditions of safety to the operating personnel and others in a manner such as to elicit responsible quantitative data on infection of small laboratory animals by the inhalation route."

A description with good photographs and diagrams of the overall installation in a building housing two cloud

chamber units, the central items of which are Reyniers "SP-4-B germ-free units," and accessory workrooms is given. This includes apparatus and methods which were so "designed that infective clouds could be generated and sampled, and animals introduced into the clouds, removed, maintained, autopsied, examined, and disposed of all in a completely closed system from all parts of which the exhaust was evacuated to an air incinerator." The efficiency of the apparatus and methods is shown by the fact that the author and his many colleagues, with numerous assistants, were free from infection during six months of intensive study employing several of the most notorious incitants of laboratory infections (*Brucella suis*, *Pasteurella tularensis*, psittacosis virus, etc.).

Basic data on the selection of atomizers for the production of clouds of labile agents and the stability and infectivity of certain highly pathogenic bacteria and viruses are given. Preliminary data are given for the dosage by inhalation resulting in infection or death in 50 per cent of the exposed animals (guinea pigs, hamsters, and mice).

The results of this study provide an excellent basis for further investigation both of the qualitative and quantitative aspects of air-borne infection and will be of interest to all concerned with the problem of spread and control of respiratory diseases of bacterial and virus etiology. This volume is the first publication under the title of *Microbiological Monographs* sponsored by the Society of American Bacteriologists.

CLAYTON G. LOOSLI

Further Effects of Added Thiamin on Learning and Other Processes
—By Ruth Flinn Harrell, New York:
Teachers College, Columbia University,
1947. 102 pp. Price, \$2.75.

This is a report of the second in a

he really seems to know what's going on. He keeps his people happy but he also has control and authority. I guess I'd call him a real administrator.

We spent some time going over the plant. I didn't know there were so many buildings there. Each building was full of people, each one working quietly and efficiently at his job, methodically and swiftly. It didn't seem like a government office in which there is loud talk and not much work and coke machines around. This seemed more like a business office.

We had lunch in the cafeteria. That was a wonderful cafeteria, good food served at low cost. It's a good idea I think.

The Sanitary Engineering program certainly made me think. The director showed me his organization chart and explained what each program was. I didn't know, for instance, that public health had any responsibility for checking food lockers and refrigerators. I knew food and drugs were controlled but I couldn't have told you who did it. I heard milk had to be pure but I just thought farms controlled this. (Bill called to his mother who was in the kitchen) Hey Mom, what kind of milk do we have? Raw milk? Do you mean Dad and I want raw milk? I guess we had better have homogenized after this. Oh, you say that it's pasteurized milk that is pure? Well I guess we'll have to have pure milk from now on. Say, there ought to be a law about pure milk if there is so much danger in raw milk. There ought to be a law preventing its being sold.

Vital statistics were kind of over my head but I guess the director knows the business. It seemed like a great deal of information was available through the work of the statisticians.

The V.D. program was a "slickie." I guess the department is doing more in V.D. than in any other program, at least it's more publicized. I knew

something about it before I went to the Health Department. We all were given blood tests at our school. I guess the department should be most proud of the venereal disease program and how they have gotten the incidence way down.

And those little trucks that go around getting x-ray pictures; that's another good program. They ought to come to our schools and give us x-ray pictures.

The man doing the epidemic work sounded like a "brain" but he's really efficient. Do you know that he gets a report on diseases each day, and each night sends out a report on the diseases to all doctors. They also do vaccinations. I thought the schools did that.

The hospital program is a good one; they are building to give some more space for laboratories. The department approves plans for hospitals. They don't? Only those where federal funds are used? Heavenly days, someone messed me up! I thought all hospitals had to be approved. I still think it would be a good plan.

And say, that EMIC man had a "dilly" of a problem too. He told me of some of his problems and he is handling them well. That's a very good program.

I had a coke with the dental man. He has lots of problems too, believe me. It was an eye-opener to know that there was a state dental program.

There were other programs too, but I couldn't talk to all the people. Some of them were out working on their jobs and sent me notes. That was nice of them, wasn't it. I'd like to go back and see more of them some day.

The people are well chosen for their jobs. I thought the way they hired people was a good deal—you get people who know something about the job. I was interested to know that people had to take examinations and that the three top people were sent to the health department for them to make their choice. That certainly saves Dr.

end of each a short summary which will save many a reader the scanning of the complete text. These chapter summaries and the final or summary chapter give the argument, the evidence against compulsory medical care or sickness insurance, the so called "health insurance" of the politicians, the alternate proposals for correcting existing inadequacies of medical service, and the declaration of ideals and methods offered by the carefully considered and expressed opinion of the American Medical Association.

The approach to the subject and the narrative of events in and out of Washington are rather too categorical and absolute to satisfy an academic mind, more because of matters not dealt with and for lack of qualification of statements than from any error or dodging of the record.

There is evidence of hurried preparation, careless proof reading, and rather poor printing performance.

The reviewer finds himself in close agreement with the main argument of the volume although disliking some of the expressions or explanations used in its support. The author has put all of the physicians of the United States in his debt for presenting so many original documents in quotation and telling his story with so little waste of words.

Any educated layman will get a better idea of the situation dealt with than he can so conveniently from any other single source.

HAVEN EMERSON

Public Health Law—By James A. Tobey. (3rd. ed.). New York: The Commonwealth Fund, 1947. 419 pp. Price, \$4.50.

This third edition of Dr. Tobey's well known work is designed to bring the last, which was published in 1939, up to date. As he says in the preface, approximately 250 judicial decisions handed down in the intervening years by courts of last resort, together with

major items of new legislation and a series of important alterations in the governmental organization of public health administration, have been incorporated.

The basic organization and chapter headings of the earlier edition are retained, but a number of new sub-titles are suggestive of the extent to which traditional legal and administrative patterns for the advancement of public health are today bursting at the seams. In Chapter IV, dealing with State Health Organization, for example, the significant influx of federal pressure for higher standards into the vacuum which is so often local government is reflected in the new sub-title "Selection of Public Health Personnel"—a discussion of civil service and other prerequisites to obtaining federal grants in aid. In Chapter V, dealing with Local Health Departments, the development of serious regional planning for public health is reflected in the new sub-title "Multi-County Health Districts." As the author points out (p. 96): "In 1945 there were in the United States 1,160 full-time local health departments serving approximately 2,100 cities and counties. The Committee on Local Health Units of the American Public Health Association has recommended that there should be 1,197 units of local health jurisdiction in this country." Other new sub-titles deal with diseases of animals and leprosy (Chapter VIII), prophylactic devices (Chapter X), Bang's Disease and filled milk (Chapter XI), enriched foods (Chapter XII), and the National School Lunch Act (Chapter XV).

Public health covers an enormous territory, as Dr. C.-E. A. Winslow's definition of the field—which the author quotes with approval (p. 4)—brings out. The task confronting one who would assemble the law relating thereto is correspondingly large, since administrative law, constitutional law, criminal

Mathews lots of work, doesn't it? having an officer with the sole job of recruiting workers. Whoever thought up the idea had a brain. I didn't know it before but I know now that only a few departments get their workers on the basis of the worker's ability and not on his political strength. I certainly wouldn't choose a doctor for his political beliefs if I were sick. And I don't think political activity is important in electing health workers.

I learned another thing—that we have a city health department which does the health work of our community. I had supposed it was done by the state. The city Health Department knows the

immediate health problems and can do something about them.

Do you know, this experience made me have a lot of faith in the Health Department and I can't describe how much I respect Dr. Mathews. He works Saturdays and week-ends and has, at times, worked all night. I don't know how one man can do all that he does but boy, he sure impressed me as being good! The work of the Health Department ought to be known by all of us citizens. When I finish college I doubt if I will work *in* the Health Department but you can be sure I'll work as a citizen and taxpayer *for* the Health Department.

Throughout the book many case examples are used of people with fictitious names. These individuals reappear from time to time in different chapters to bring out illustrative points, but it is done in such a way as to show some continuity between their stories and their acquaintance with or relation to other individuals in the same community and still remain illustrative of the scientific material being presented. The simplification which is desirable of course, from the standpoint of the lay reader, nevertheless lends itself to broad generalizations to which there may be specific exceptions as the author is well aware.

In general this is a well written and well presented psychoanalytic interpretation of mental phenomena. The only criticism which can be made is the question of the desirability of including the appendix on mental telepathy, intuition, etc., in a book for lay persons. While there is no doubt that the phenomena included under this are legitimate problems for scientific investigations, the extent to which this has gone does not seem to warrant an exposition of these phenomena in this simplified manner. Because of the many notions around these subjects in the mind of the lay public, it would have been better to omit this appendix. The author also makes some very broad generalizations with regard to the qualifications of psychiatrists. His intention was that of providing the layman with a basis of judging professional qualifications when seeking help.

JAMES M. CUNNINGHAM

Nursing in Tuberculosis — By Louise Lincoln Cady, R.N. Philadelphia, Pa.: Saunders, 1948. 481 pp. Price, \$3.75.

This is the sort of book nurses like because it is written for nurses by an experienced nurse who is a specialist in the field. Those sections which describe

tuberculosis in its clinical aspects and outline treatment procedures offer fairly familiar material, brought up to date however, but the real value of Mrs. Cady's presentation lies in her approach to tuberculosis as a public health problem and to the tuberculous patient as a member of his family and community. In a sense, Mrs. Cady has succeeded in generalizing a specialty, linking tuberculosis, its prevention and cure, to all nursing activities in homes and hospitals.

Another outstanding feature of this book is the emphasis upon the nurse's responsibility as a teacher. There is hardly a page which does not contain reference to information which must be given to the patient for his own welfare and the protection of others. The words "explain," "interpret," "show," "reassure," and "teach" occur again and again. The suggestions are concrete and simple and take into account the state of mind of the sufferer. The instructions regarding the meaning of bed rest seem unusually sensible and appropriate and revise many of our older ideas regarding it. Nurses will find chapter XXIII, Mental Hygiene, especially pertinent in understanding the mental attitudes of the tuberculous patient and his family, and chapter XXVI, The Tuberculosis Clinic, full of practical suggestions growing out of first-hand experience.

The only real criticism which is worth noting, aside from a few statements which might be considered the author's personal opinions—and who has a better right to make them?—is the *structure* of the book which can only be described as confusing. Nursing aspects of care appear here, there, and everywhere. Medical and surgical procedures in treatment are at times separated by ten chapters, at others crowded into one paragraph, and an orderly presentation of the course of the disease and its accompanying de-

Credit Lines

WHO AND CHOLERA IN EGYPT

"In a remarkable demonstration of how nations can coöperate against a common danger, cholera was confined to Egypt and brought under control in six weeks," says the December *News Letter* of the Interim Commission of WHO. The procurement of medical supplies was coördinated in the New York office which shipped by air more than 32 tons of vaccine, blood plasma, and other supplies urgently needed for the treatment and prevention of cholera. Cholera vaccine was made available by the United States, China, Indo-China, Japan, and Southern Korea. This meant arranging with United States manufacturers for new supplies of about 3,000,000 cc. of vaccine. In addition, 11 governments sent the Egyptian Government directly vaccine from supplies on hand as soon as they were advised of the outbreak. Thus Egyptian public health authorities were able to complete their anti-vaccination program by the end of November, nine weeks after the first outbreak was reported.

In procuring and shipping supplies to Egypt and neighboring states, WHO advanced nearly \$150,000 for later repayment by the governments involved.

The epidemic did not gain a foothold in the cities and was confined largely to the Nile Delta. Furthermore, the case fatality rate was less than 50 per cent compared to an apparent rate of 85 per cent in the 1902 epidemic. "This is due primarily," says the WHO report, "to the tremendous efforts of the Egyptian public health authorities backed up by the resources of many nations coöperating through WHO." Another illustration of the fact that coöperation is automatic to meet a crisis but less active to prevent one in the indefinite future.

SAVING EVERY PERMANENT TOOTH

The Dental Division of the Kansas State Health Department, Leon R. Kramer, D.D.S., Director, makes an interim report on its program. In a number of schools of the state, it has in operation a program for saving the teeth of school children. In 1945, the Baldwin Elementary School, after carrying on the program for five years, for the first time, reported no loss of permanent teeth among its 184 children enrolled.

In 1947, the Prairie School, with 485 children enrolled, reported that not a single child had lost a permanent tooth except in two instances for orthodontic reasons. For five consecutive years this school had attained 100 per cent correction of dental defects.

The program consists of an annual dental examination in the schools made by local dentists. Included also are classroom instruction, follow up activity, free dental care for children unable to pay, and excused absence from school on request of dentist to fill dental appointments.

ESOTERICA

The November issue of *Ciba Symposia* which is published for the interest of the medical profession by Ciba Pharmaceutical Products (Summit, New Jersey) is devoted to "The Prescription—from Antiquity to the Renaissance" with many interesting facts and illustrations for the antiquarian. The text is by G. Kasten Tallmadge, M.D., Ph.D., and the illustrations are taken from a variety of ancient documents.

JUNIOR LEAGUE SPONSORS BLOOD CENTER

Milwaukee (Wisconsin) reports an interesting example of lay agency contribution to community needs. The Milwaukee Junior League has opened a

Vice-President—

Louis P. Gebhardt, M.D., Professor of Bacteriology, University of Utah, Salt Lake City, Utah

Ann W. Haynes, State Department of Public Health, San Francisco, Calif.

Dorothy Teal, Honolulu, Hawaii

*Secretary-Treasurer—*Walter S. Mangold, Associate Professor of Sanitary Practice, University of California, Berkeley, Calif.

New Regional Board members of the Western Branch for two year terms include:

Robert A. Downs, D.D.S., Denver, Colo.

Stewart S. Murray, M.D., Vancouver, B. C.

James M. Doughty, Santa Fe, N. M.

John Wright, Boise, Idaho

Adolph Weinzirl, M.D., Portland, Ore.

Among other activities, the Regional Board voted to combine the office of Secretary and Treasurer, and a special resolution of appreciation was presented for the long service as Treasurer of Guy S. Millberry, D.D.S., of Los Gatos, Calif. The 1949 meeting of the Western Branch will be held in the Southwestern District, including Arizona and Southern California, at a date to be determined, presumably in May.

SOUTHERN BRANCH A.P.H.A. MEETS IN NEW ORLEANS

The Southern Branch, A.P.H.A., held its Annual Meeting in New Orleans, La., April 12, 13, and 14. During the three day meeting sessions were held by the Health Officers, Public Health Nursing, Dental, Biology, Health Education, Laboratory, Statistical and Clerical, and Sanitary Engineers-Sanitary Officers Sections, and three General Sessions took place.

The First General Session, which was the opening session of the meeting, featured addresses of welcome, a paper on World Health Organization by Martha M. Eliot, M.D., one on Hemisphere Health by W. W. Peter, M.D., and a Panel on School Health with Dean F. Smiley, M.D., as Moderator. The Second General Session was a general assembly conference on the subject "Evaluation of Local Health Work." At the Third General Session the topics covered were Fluorides in Preventive Dentistry, Health Educa-

tion for Legislatures, and Newer Aspects of Public Health Nursing.

Six hundred delegates from the states comprising the Southern Branch area attended the meeting, and the American Public Health Association was represented by Reginald M. Atwater, M.D., Executive Secretary, Roscoe P. Kandle, M.D., Field Director, and William T. Ingram, Engineering Field Associate.

Each of the eight Sections elected a Chairman, Vice-Chairman, and Secretary. Officers for the Branch were elected as follows:

*President—*John M. Whitney, M.D., New Orleans, La.

*1st Vice-President—*Robert H. Riley, M.D., Baltimore, Md.

*2nd Vice-President—*A. Pearl Barclay, R.N., Montgomery, Ala.

*3rd Vice-President—*Lucy S. Morgan, Ph.D., Chapel Hill, N. C.

*Secretary-Treasurer—*George A. Denison, M.D., Birmingham, Ala.

blood center which it has underwritten for five years on a non-profit basis. The Center has been approved by the Milwaukee County Medical Society, and private hospital blood bank facilities have been turned over to it. The medical director is Tibor J. Greenwalt, M.D., who will have the assistance of technical personnel and Junior League volunteers.

50 COMPULSORY SICKNESS INSURANCE BILLS IN 16 STATES—DEFEATED

The Research Council for Economic Security (105 West Monroe Street, Chicago 3) has recently published a pamphlet, illustrated with graphs, analyzing the 50 compulsory cash sickness and related bills that were introduced in the 1947 legislatures of 16 states. This is five times the number of such bills introduced a decade ago. All of the bills were defeated, one having passed a state legislature only to be vetoed by the governor.

The Council takes this to mean, not a decreasing demand for this type of legislation, but rather uncertainty in the minds of legislators as to what type of plan is best. Says the report, "The recent trend toward greater activity is likely to continue. This pamphlet is issued in the realization of the need for paying close attention to those developments."

NEWS ON THE CANCER FRONT

Several items of interest in the cancer world have recently come across the Credit Lines Editor's desk.

The *Cleveland News* of October 23 reports that in Mansfield, Ohio, a co-operative cancer clinic has been opened that "is pacing the nation . . . to track down early cancer invasion." Among its reported unique features is that it brings together assorted community agencies that have hitherto been virtually strangers, that it is the first Ohio clinic to win financial support from the State Department of Health, that it has been set up

by the Richland County Medical Society, and receives support from the American Cancer Society, from the Mansfield General Hospital, and from city and county health departments. More details can be secured from Fred O. Tonney, M.D., Richland County Health Commissioner, Mansfield, Ohio.

In New York City, the first cancer detection clinic to be operated by the municipal department of health is reported (Kips Bay-Yorkville Health Center, 411 East 69th Street). This is a diagnostic clinic purely for referral of patients requiring medical attention to private physicians or other clinics. Here too, the effort is coöperative, the New York City Cancer Committee, Cornell University Medical College, and the Strang Cancer Prevention Clinic of Memorial Hospital sharing sponsorship. The director is Emerson Day, M.D., Assistant Professor of Public Health and Preventive Medicine, Cornell University Medical College.

The Public Affairs Committee has revised its *Pamphlet No. 38* on Facing the Facts about Cancer. This brings up-to-date the figures on cancer incidence and the information on cancer organizations and their activities which have expanded extensively since the pamphlet was first produced. Available from Public Affairs Committee, 22 East 38th Street, New York 16. 20 cents each; special rates on quantity orders.

"TIC" CONTINUES TO TICK

Tic, the enterprising magazine of a commercial dental prosthetics manufacturer that discusses the social aspects of dentistry and which has previously been mentioned in Credit Lines, devotes its November, 1947, issue to the story of the Cleveland Health Museum. Prepared by Henry A. Hartman, D.D.S., Health Officer, of Parma, Ohio, and illustrated with many photographs of the museum's exhibit, this brings the story of the Cleveland Health Museum

NEWS FROM THE FIELD

DR. CHISHOLM DIRECTOR OF WHO

At the first session of the World Health Assembly held in Geneva, June 24-July 24, Brock Chisholm, M.D., was elected Director General of the World Health Organization. Dr. Chisholm has been Director of the Interim Commission which has carried on world health activities until the charter was ratified and the first organization meeting held. A Canadian and a psychiatrist, he has indicated in a number of addresses his interest in physical and mental health as a means to world peace.

At the first session of the Assembly, Dr. Andrija Stampar of Yugoslavia, who had served as Chairman of the Interim Commission, was elected President of the Assembly by acclamation. Sir Aly Tewfik Shousha, Pasha, of Egypt was elected Chairman of the Executive Committee.

As of July 15, the membership of WHO numbered 68 countries, 11 of which are not yet members of the United Nations. The United States House of Representatives voted ratification of the WHO Constitution just in time for this country to be represented at the first World Health Assembly. In spite of its addition of a one year withdrawal clause, the Assembly voted to accept the ratification of the United States. Thomas Parran, M.D., former Surgeon General of the U. S. Public Health Service, who headed the 33 member delegation of the United States, assured the delegates that his country "stands solidly behind the World Health Organization and its objectives."

Among the matters agreed upon in the Assembly were the declaration of principle that WHO should in no way interfere in local affairs but confine itself to strengthening national health admin-

istrations in their efforts to deal effectively with the problems that faced them. Priority was granted to four programs for 1949, combating malaria, tuberculosis, and venereal disease on a global scale, and the improvement of maternal and child health. With respect to malaria, it was proposed that governments offer free therapeutic and prophylactic treatment; for tuberculosis the use of BCG vaccine was recommended and the establishment of an expert BCG panel. The United States and Mexico proposed an expert committee to combat water-borne and milk-borne diseases; an international study of cancer and other diseases was also proposed. A preliminary report on WHO's survey of the world's insulin supply was made, including the hopeful aspect due to the Lindner method of preserving the pancreatic glands of slaughtered animals, from which insulin is made. WHO is publishing this method in full.

Establishment of a world influenza center in the London National Institute for Medical Research was recommended, as were international centers in other areas for the study of brucellosis and schistosomiasis. The question of establishing a WHO medical supply bureau will also be studied for report to the next meeting of the Assembly.

Geneva was unanimously selected as WHO permanent headquarters, and regional offices were recommended for the Eastern Mediterranean, Western Pacific, Southeast Asia, Europe, and Africa, with negotiations in process to integrate the Pan American Sanitary Bureau with WHO as the regional office of the Americas.

The United States delegation included the following:

to a new audience. *Tic* is available from Ticonium, 413 North Pearl Street, Albany, N. Y. at 25¢ per copy, \$2.50 per year.

HAVE YOU A PROBLEM CHILD?

The American Academy of Pediatrics announces that it has written and produced a new 16 mm. sound film on the "Problem Child." With a running time of about 25 minutes, it deals with feeding schedules, food and toilet habits, discipline, parental attitudes, etc. It is intended primarily for special lay groups such as Parent Teacher Associations. It is being distributed free of charge to both lay and medical groups by the Pet Milk Company, Research Division, St. Louis 2, Mo.

The picture was made possible by a grant of funds from Pet Milk to the Academy. In requesting the picture, prospective users are asked to give the date when the film is to be shown and to allow at least three weeks for handling the order.

HEALTH PROGRAM AIDS

Agenda began publication in July, 1947, as "the magazine for women's club leaders" with the purpose of furnishing aids in program making for women's clubs.

The second issue, September, 1947, carried two articles, one on "Better Health in Your Community" by Surgeon General Thomas Parran of the U. S. Public Health Service, and another on "How To Form a Health Council" which was the case history of the development of the public health lay committee of Montgomery County (Maryland).

Number 3, for November-December, has an article by bandleader Kay Kyser on "How to Make People Health-Conscious" in which he reports on some of the publicity aspects of the Good Health Campaign being carried on by the North Carolina Good Health Association.

Another article on "'Selling' Health Through Movies" is the story of the movie health program in Houston, Tex. Apparently pages 24 and 25 of these issues are being reserved for health matters.

The magazine is published by the Printers' Ink Publishing Company, 205 East 42nd Street, New York, but it is not sold either at subscription prices or on newsstands and it is reported that back issues are no longer available. The magazine, however, is distributed to practically all public libraries. Write to the publisher if you are interested in knowing how to get on the distribution list.

TELEVISION HEALTH EDUCATION

The American Medical Association, conscious of its history as a pioneer in health education by radio, is preparing for television. The Associate Director of its Bureau of Health Education, William W. Bolton, M.D., has prepared a small 22 page pamphlet, *Television Handbook*. This outlines the problems and form of presentation of health education through television and summarizes some 30 television programs that have been given.

The A.M.A. has also had a second printing of its radio handbook, first published in 1946. The two handbooks are alike in format and printing.

The handbooks are available from the American Medical Association, 535 North Dearborn Street, Chicago 10. 50 cents per copy; quantity prices on request. Sample copies will be furnished to official and voluntary health agencies.

WHERE EACH TOWN STANDS

It is well known that Connecticut has no full-time local health officers except in 13 cities comprising about half of the state's population. All the rest of its 169 towns, all but 21 with populations of less than 20,000, have part-time

Nursing Education in Chicago in June, the following officers for the three organizations were elected:

AMERICAN NURSES ASSOCIATION

President—Pearl McIver, R.N., Chief, Office of Public Health Nursing, U. S. Public Health Service

1st Vice-President—Janet M. Geister, R.N., Organization Consultant, Chicago

2nd Vice-President—Mrs. Bethel J. McGrath, R.N., Powers Dry Goods Co., Minneapolis

Secretary—Mrs. Linnie Laird, R.N., Executive Secretary, Oregon State Nurses' Association

Treasurer—Lucy Germain, R.N., Director of Nurses, Harper Hospital, Detroit

NATIONAL ORGANIZATION FOR PUBLIC HEALTH NURSING

President—Ruth W. Hubbard, R.N., General Director, Visiting Nurse Society of Philadelphia

1st Vice-President—Ruth B. Freeman, R.N., Administrator of Nursing Services, American National Red Cross

2nd Vice-President—Mrs. Carl B. Grawn, Board Member, Visiting Nurse Association of Detroit

Treasurer—L. Meredith Maxson, Vice-President, First Boston Corporation, New York

Secretary—Anna Fillmore, R.N., General Director, National Organization for Public Health Nursing

NATIONAL LEAGUE OF NURSING EDUCATION

President—Agnes Gelinas, R.N., Chairman, Department of Nursing, Skidmore College

Vice-President—Mrs. Hazelle B. Macquin, R.N., Dean, School of Nursing, University of Utah

Secretary—Mrs. Henrietta A. Loughran, R.N., Director, School of Nursing, University of Colorado

Treasurer—Henrietta Doltz, R.N., Department of Nursing, University of Oregon Medical School

PROPOSAL TO CONTINUE NATIONAL HEALTH ASSEMBLY

Three proposals to carry out the recommendations of the National Health Assembly, held in May, were made by its Executive Committee, meeting late in June:

1. That the Assembly's Executive Committee continue as an advisory and coordinating agency;
2. That the Federal Security Administrator appoint a small working subcommittee to

recommend to the full committee plans on public education relating to health, and on continuing organization and financing;

3. That each state be urged to hold a health assembly, patterned after the National Assembly, and giving equal representation to professional and "consumers'" groups in order to stimulate the widest possible co-operation among all concerned in health; that these state conferences, in turn, stimulate local conferences along the same lines to develop essential local planning and operation of health services.

As a means of exploring practical methods of carrying out the Health Assembly's recommendations, the Federal Security Administrator, Oscar R. Ewing, has asked the subcommittee to consider:

Publication of the final recommendations of the 14 Sections constituting the National Health Assembly;

Exploring methods for follow-up of recommendations made by the Sections of the National Health Assembly—wherever possible, such follow-up should be carried on by organizations already specializing in these fields of activity;

Development of plans and guidance for state and local health assemblies.

HONORARY DEGREE TO DR. ELIOT

Martha M. Eliot, M.D., President of the A.P.H.A. and Associate Chief of the U. S. Children's Bureau received the honorary degree, Doctor of Humane Letters, at the Commencement exercises on June 21, of the University of Rochester. In presenting Dr. Eliot for the degree, Janet Clark, Professor of Biophysics and Dean of the College for Women of the College of Arts and Sciences, said:

When we contemplate the slow progress that the world is making towards political unity we are often discouraged. It is with particular thankfulness that we turn to fields in which notable progress has been made towards bettering the conditions of the human race. Nothing is more inspiring than the great strides made in the last fifty years in the field of public health. The men and women who have devoted their lives to controlling disease have fought a battle for the conservation of human lives and resources, not their destruction. The contribution they make often

health officers, and many of them have other personnel.

In the November *Connecticut Health Bulletin*, James A. Dolce, M.D., Chief of the Division of Local Health Administration, analyzes the 1946 expenditures for health services of the 169 towns and cities of the state. He finds that they spent an average of 88 cents per capita; 94 cents in towns of less than 1,000 population, and \$1.10 in cities of 50,000 or over, with towns between 2,500 and 20,000 averaging the least, 63 cents. One town of 300 persons spent \$4.20 and another of 1,300 spent \$18.

These cold figures are a telling argument for the consolidation of towns into health districts, for a part of the cost of operating which a new Connecticut law now provides.

CHRONICLING WORLD HEALTH

Volume 1, No. 1-2 of the *Chronicle of the World Health Organization* appeared recently. It aims to be "a readable summary of the activities of WHO" and "to mark the stages in the attempt to implement, through international action, the declaration of its Constitution that 'the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being.'"

Published in the five official languages of UN, its subscription is \$2 for 1947, and is available from the WHO Interim Commission Headquarters Office, 350 Fifth Avenue, New York 1. Specimen copies sent free on request.

FROM BOWDITCH TO GETTING IN MASSACHUSETTS

The first 75 years of the Massachusetts Department of Public Health, completed in 1944, have now been set down for future students and historians in a special number of *The Commonwealth*, a publication of the department. Entitled "75th Anniversary of the Massa-

chusetts Department of Public Health, 1869-1944," it is written by Raymond S. Patterson, PhD., Director of Health Education, John Hancock Life Insurance Company, assisted by Mary Carr Baker, Supervisor of Health Education in the Massachusetts Department of Public Health. It has the unmistakable Patterson flavor familiar to *Journal* readers through his *Selected Public Health Bibliography with Annotations*.

Using the surveyor's technique as analogy, the authors divide their story into five bench marks, 1869, 1879, 1886, 1914 and 1936, giving the influences and events of each and relating the Massachusetts story to that of public health in the United States. There are pictures of the 8 state health commissioners (or secretaries of the state board of health) from Bowditch in 1869 to Getting of today.

This pamphlet of some 70 pages should be in every library as a part of the permanent record recalling the establishment of the first state board of health in the United States. Though the report does not so indicate, it is presumably available from the Massachusetts State Health Department, State House, Boston.

OKLAHOMA'S MERIT SYSTEM

As a result of the Credit Lines items about Oklahoma's 6th annual *Merit System Council Report* (Jan, 1947, p. 98), it has been reported that a number of health officers requested the pamphlet and were stimulated to get further information about merit systems.

The 7th *Report* for the year ending June, 1947, is now at hand. It maintains the high standard set in the earlier, doing a particularly good job of simplifying in layman's language and with humorous illustrations some questions and answers about the merit system's advantages to worker and public.

Some indication of the extent of Oklahoma's Merit System operation is that

by the National Organization for Public Health Nursing at its closing business session on June 4, 1948, during the Biennial Nursing Convention in Chicago:

WHEREAS, the people of the United States are not at present receiving adequate public health care, and

WHEREAS legislation has been introduced in the Congress of the United States to permit federal assistance to states in the development of local public health services, passage of which would improve and extend the nursing care available to the people of the United States, be it therefore

RESOLVED that the N.O.P.H.N. approve the principle of legislation to provide aid to states in the development of local public health services and urge members to support aggressively such legislation as is presently proposed or may be subsequently introduced to achieve this end, and to interpret to other civic groups the import of such legislation and the urgency for public action in support of it.

NEW YORK STATE HOLDS ANNUAL HEALTH CONFERENCE

The 44th Annual Health Conference under the auspices of the New York State Department of Health was held in Saratoga Springs July 21-23. More than 1,000 health officers, public health nurses, and engineers were in attendance.

Among the out of state speakers were Dr. Leonard A. Scheele, Surgeon General, U. S. Public Health Service, Washington; Dr. Austin M. Brues of the Argonne National Laboratory, Chicago, Ill.; Dr. William Roemmich, Minneapolis, Minn.; Dr. Frederick J. Stare, Harvard School of Public Health, Boston; Dr. W. H. Sebrell, National Institute of Health, Bethesda, Md.; Dr. Vlado A. Getting, Commissioner of Public Health, State of Massachusetts, Boston, and Dr. Ernest L. Stebbins, School of Hygiene and Public Health, Johns Hopkins University, Baltimore.

A new mobile X-ray truck was delivered to the State Department of Health during the conference and keys to the unit were presented to Dr. Herman E.

Hilleboe, who said that the truck was provided in order that services may be brought to people where the people cannot be brought to the services. The unit was put into operation in making photofluorographs of the chest of those in attendance at the conference.

NEW YORK STATE TO BUILD VIRUS LABORATORY

The New York State Department of Health at Albany announced on July 20 that construction would begin immediately of a new virus laboratory as an addition to the present laboratory on New Scotland Avenue, Albany. Dr. Herman E. Hilleboe, State Commissioner of Health, said that facilities would be provided for the Department's research program in virus diseases and other activities.

DR. VAN HEUVELEN BECOMES SUPERINTENDENT OF HEALTH IN SOUTH DAKOTA

The appointment of Gerald John Van Heuvelen, M.D., as Superintendent of Health in South Dakota, effective July 1, was recently announced. Dr. Van Heuvelen succeeds Gilbert Cottma, M.D., who has retired.

Dr. Van Heuvelen is a graduate in medicine of Rush Medical College in 1932, and is a diplomate of the National Board of Medical Examiners in the same year. He has for some time limited his practice to public health and has served as Assistant Superintendent and Epidemiologist in the South Dakota State Department of Health.

KATHARINE LENROOT RECEIVES UNIVERSITY HONORS

Katharine Lenroot, Washington, Chief of the U. S. Children's Bureau, received on June 2, the degree of Doctor of Laws from Tulane University, New Orleans, at the Annual Commencement. The citation reads:

One of the outstanding women in American public life, Miss Lenroot is known throughout the world for her distinguished work in be-

there were about 5,500 applications for examinations, of whom about four-fifths were accepted. Fewer than three-fourths of those accepted appeared for the examination and about three-fourths of these passed. Thus more than twice as many applications were processed in order to get about 2,500 eligible candidates for state positions.

The public health nursing shortage is highlighted by the fact that of 25 nurses applying for two examinations, 23 were accepted but only 5 appeared, all of whom passed the examination. Fewer than half of sanitation personnel accepted for examination appeared but all who took the examination passed. A total of 83 persons applied for health unit clerk examinations; 51 were accepted; 12 appeared for the examination and only 6 passed.

If more merit system administrators prepared such understandable reports, much of the prevailing mystery about merit systems would be dispelled.

SAYING IT WITH PICTURES

The extent of tuberculosis in Alaska, where the death rate in 1945 was nearly 9 times as great as in Continental United States, has been widely discussed in recent months. That some action is being taken is indicated by *Home Care of the Tuberculous in Alaska*. This is an excellently printed pamphlet in words and pictures that tell the story of fisherman Brown's 16 year old daughter, Sally, who contracted tuberculosis, was diagnosed at an early stage and recovered after a long period of home care.

The homely details of sterilizing dishes, preparing the patient's bed, taking temperatures, and all the necessary improvising that are a mystery to the average uninfected family are told step by step in words and photographs of actual people in an Alaskan home.

The handbook is the result of cooperative effort by the Alaska Native Service, the Alaska Tuberculosis Asso-

ciation, and the Territorial Health Department, with assistance from the U. S. Public Health Service and the U. S. Indian Service.

Available from the Alaska Tuberculosis Association, Juneau, \$1.50.

HEALTH SERVICES IN BRITAIN

Britain's National Health Service Act became law in November, 1946, and will come into full operation in mid-1948. The Reference Division of the British Information Services is distributing a pamphlet with the above title which in concise and simple form explains the new Act, how it has developed, how it will work, and what it will provide. It gives particular attention to the effect the new Health Center Scheme will have on the role of the general practitioner as well as the interrelation of the various medical and public health services.

As to the historical background of the National Health Service Act, the pamphlet says:

The National Health Service aims at ensuring that everyone in Britain, irrespective of means, age, sex, or occupation, shall be entitled to the best and most up-to-date care available. This universal concept of national health services is an innovation, but it is not revolutionary.

It is a logical development showing continuous evolution over the past centuries from Government measures to check the spread of pestilence to the modern concept of maintaining the health of the individual, whether he is a menace to the community or not.

Available without charge from the British Information Services, 30 Rockefeller Plaza, New York 20.

THIRTY YEARS OF UNION MEDICAL SERVICES

Coinciding with its announcement of a million dollar expansion program, the Union Health Center of the International Ladies Garment Workers Union of New York City (275 Seventh Ave.) recently issued a *Triennial Report* for

the years 1944-1946. This three year report traces the history of the Center's service in the more that a quarter of a century since it started giving service.

In 1916 the medical services were limited to the amount of work a general medical doctor could do with the aid of his stethoscope and his medical knowledge. In 1916 total services numbered about 7,000; in 1946 nearly 208,000. In the intervening years, 12 specialized clinics had been added and the worker's fee of \$1 now includes not only the basic physical examination but laboratory and x-ray tests, physical therapy treatments, and service in specialty clinics.

The Union now has a complete health and welfare service based upon a pre-paid medical plan. Its experience and that of similar plans like the CIO Labor Institute in St. Louis has much to offer the developing programs of medical care, industrial and other.

THE MENTAL HEALTH PROGRAM

There are now reported to be 8,000,000 persons in the United States suffering from some form of nervous or mental illness. Moreover, since the incidence of mental disease rises with age, an increase is forecast for the coming years. Which makes it none too soon that there is now a three-way national mental health program in operation, authorized by the 79th Congress in 1946 and implemented by Congressional appropriation of \$7,500,000 in 1947.

Over a million dollars annually will be made in grants to public and private non-profit institutions for the development and improvement of facilities for training mental health personnel. Nearly half a million will be spent on grants-in-aid to similar institutions for research in the mental hygiene field. Three million dollars is earmarked for grants-in-aid to the states for development of local mental health programs, particularly for the development of traveling mental hygiene clinics in sparsely settled rural

areas, areas which have had practically no facilities at all. The goal is one outpatient mental health clinic for each 100,000 of the population as soon as personnel is sufficient to meet this demand.

Other activities to be carried out through the national mental health program are field studies, inservice training for general practitioners, and administration of hospitals for the mentally ill. An appropriation of \$850,000 has also been made for a site for the National Institute of Mental Health to be constructed in Washington.

In December, 1947, on recommendation of the National Advisory Mental Health Council, a grant was made to the International Committee on Mental Health for a study of the effects of war, the report to be presented at the August International Congress on Mental Health in London. A grant was also made to the National League of Nursing Education to set up a professional accrediting body in the field of psychiatric nursing.

CHILDREN'S FUND OF MICHIGAN

The *Eighteenth Annual Report* of the Children's Fund of Michigan for the year ending April 30, 1947, is of particular interest because of its paragraph on county health departments which says in part, "For the first year no appropriations were made to numerous county health departments that at the time of their origin were promoted and subsidized by the Children's Fund . . . Each county or district health department has continued to receive its annual appropriation from the supervisors and no health unit established by the Children's Fund has ceased operations or failed to carry on a reasonable good program . . . and have become integrated into the county government and county life."

This led the Credit Lines Editor to look into earlier reports. He found that

the first help to local health units was less than \$8,000 to two four-county units in 1930. The next year, four units received more than \$60,000; the next year five received more than \$75,000. Year by year aid was extended until the peak of 1940 when \$210,600 was given to 19 health units involving 41 counties. Since then the program has declined until the current year when all the units stood on their own local governmental feet, as it were. This would appear to be an outstanding example of pioneering, one of the basic functions assigned to voluntary agencies by the Gunn-Platt Report.

STANDARDS FOR LOCAL HEALTH DEPARTMENTS

Effective October 1, 1947, the California State Board of Health adopted standards and recommendations for local public health departments as a basis for the allocation of the \$3,000,000 appropriation made by the 1947 legislature for the development of local health services. These standards were first recommended by the California Conference on Local Health Officers before adoption by the State Board.

Although California is perhaps not unique in having established definite standards for local health departments as a prerequisite to state aid, the methods of their adoption and their general outline might serve as a stimulus or a guide to other states in developing such definite standards.

The first requisite is that there shall be a full-time medical health officer except that counties with populations of less than 25,000 with a part-time health officer may be given provisional approval until June 30, 1948, while a plan for full-time service by joining with contiguous counties or by some other means is developed.

A local health department must maintain a headquarters office on a full-time basis, must have a clerical staff under

proper supervision, a public health nursing staff under supervision (one nurse per 5,000 population is recommended; if school nursing is included, one per 3,500; and if bedside nursing also, one per 2,000), an adequate sanitation staff with at least one worker per 20,000 population recommended; and must carry on the six basic standard health services.

Available from California State Department of Public Health, 760 Market St., San Francisco 2.

LOOKING AT LOCAL GOVERNMENT AGAIN

The local government studies of the Council on Intergovernmental Relations have previously been mentioned in *Credit Lines* (1946, pp. 184, 1327; 1947, p. 601). Further details have now been published. In September, the National Council on Intergovernmental Relations, Washington, D. C., published *Grass Roots: A Report and An Evaluation*. It gives the backgrounds of the Spelman Fund supported project to strengthen local government by rationalizing it.

This pamphlet tells how the five counties in which the experiment is being carried on—Blue Earth, Minnesota; Henry, Indiana; Colquitt, Georgia; Santa Clara, California; and Skagit, Washington—were selected, how the local councils were set up and given responsibility.

In each of the counties, the mosaic of political pieces that make up the sum total of local government are analyzed and a program of coöperation between them put into effect. Contrary to previously accepted easy judgments not all the confusion is due to the federal government's operation in a local area.

Following the earlier *Blue Earth County Report* mentioned in *Credit Lines* of February, 1946, a later one, *A Study of Public Health Administration*, has been issued. It found that in this county of fewer than 40,000 per-

sons, there were 24 health officers, 6 public health nurses, divided among 5 jurisdictions but none in either towns or villages.

These studies are worth following. In their various approaches they all add up to more coördination of local government rather than transferring responsibilities to state or federal governments.

TYPHUS IN WORLD WAR II

The December, 1947, issue of the *Military Surgeon* carries the article "Typhus on The Western Front in World War II" by Lt. Col. Hartwin A. Schultze, M.C. That typhus did not develop into a major cause of morbidity and mortality during the last war is attributed to the skill and united efforts of the military and civilian personnel working in preventive medicine and public health. Colonel Schultze gives a brief account of what some of these preventive measures were as undertaken by the military forces. Aside from military organization and administration, he attributes the remarkable control of typhus to the use of immunizing vaccine and DDT.

THE HEALTH STORY IN HAWAII

In a pocket size pamphlet of about 100 pages, the Public Health Committee of the Honolulu Chamber of Commerce tells Hawaii's current health story. In brief text and in photographs, it tells what are the chief health problems and the various health services available to meet these problems. Background data on industries, population, schools and the island's history are included. It may surprise Mainlanders to discover that for tuberculosis and typhoid alone among a dozen infectious and parasitic diseases, the death rates are higher in Honolulu than in Continental United States. This little booklet should serve as a useful health education tool for the Hawaiian population but also has good capsule information for the visitor.

Its photography and printing are uniformly good. R. G. Nebelung, Dr.P.H., is the Executive Director of the Public Health Committee.

NEW YORK H.I.P. BURGEONS

The Health Insurance Plan of Greater New York has been developing so rapidly that three of its 25 groups have begun to publish bi-monthly bulletins to keep their members informed, as well as a means of health education. *Doorway to Health* of the Central Medical Group of Brooklyn (membership 8,000) first came out in September, *To Your Health* of the Central Manhattan group and *Richhaven Medical Group Review* of the Richhaven, Queens Group, in November. They represent an interesting illustration of closing the language gap between professional and layman.

H.I.P.'s enrollment at the end of 1947 was 110,000.

CONSUMERS UNION ON HEALTH MATTERS

Credit Lines has been delayed in acknowledging receipt of *Consumers Union Reports*. Early in 1947, its health and medical section which is under the general supervision of its medical adviser, Harold Aaron, M.D., was enlarged. Each monthly issue has a scientific discussion in simple language of some medical problem, particularly one around which superstitions and old wives' tales or a great curtain of secrecy have developed. It is also on the lookout for quackeries and exaggerated claims.

Samples of its articles are: *The Irritable Colon* (April), *Tonsillectomy in Children* (May), *The Problem of Infertility* (July), *Government and Medicine* (April), and *The Rise and Fall of Fleischmann's Yeast* (September).

BUSINESS CONCERNS WILL HELP TOO

The Massachusetts State Department of Health, with the financial assistance

of the United-Rexall Drug Company, has prepared and distributed a *Handbook for Physicians*, which presents in condensed form the services offered to physicians by the Department of Public Health and the facts a physician should know concerning the practice of medicine in the state. The Professional Relations Department of the drug company helped in the preparation of an appendix that includes a compilation of Massachusetts laws of interest to the medical profession.

WORTH ACQUIRING

Help Fight Tuberculosis—A Story for You—a new booklet of information on tuberculosis intended for elementary school children. Its language, format, and printing are all suited to the youthful reader who, it is presumed, will take the story home as well. Published by the National Tuberculosis Association and available from state and local associations.

Dental Health Program for Elementary and Secondary Schools—prepared by the Council on Dental Health of the American Dental Association is the first part of a manual on the dental health program to be prepared. Later pamphlets will cover prenatal and preschool dental health programs. The present pamphlet discusses the financing, administration, and lay education and participation in a dental health program. The printing is excellent and black and white illustrations help to carry its message.

Sample copies free and quantity orders at 15 cents per copy from the American Dental Association, 222 East Superior Street, Chicago 11.

UNESCO and You: A Six-Point Program—This is described as "questions and answers on the How, What, and Why of your share in UNESCO." The six-point program for individuals gives

suggestions on how to help rebuild war devastated schools and libraries, how to make personal opinion felt on the side of peace, how to train the younger generation in peace, how to dramatize UNESCO's aims in one's community, how to take part in its continuing adult education, and how to establish inter-racial and inter-religious understanding in a community. Available from the U. S. Government Printing Office, Washington 25. 15 cents.

Broken Homes—This 135th pamphlet of the Public Affairs Committee has as its thesis that tightening divorce laws is a mistaken attempt to apply legal remedies to a problem that is sociological and mental. "A modern marriage must be held together from within rather than from without," says the author, George Thorman.

This same agency's *When You Grow Older* is another recent publication and is a plea for the young and middle aged, to prepare themselves for retirement age not merely with the old fashioned copy-book thrift but chiefly with something interesting to do and with learning to live with one's age as to diet, exercise, etc.

Public Affairs Committee, 22 East 38th Street, New York 16. 20¢ per pamphlet; less in quantity.

Social Service and Rehabilitation in a Tuberculosis Sanatorium—Credit Lines is indebted to one of its Fellows, Lillian Wurzel, Medical Social Worker of the Los Angeles Tuberculosis Sanatorium of the Mt. Sinai-Duarte National Medical Center, for this symposium by the staff members of the sanatorium. It deals with the "mind-salving measures" necessary to the cure of the patient in addition to medical and surgical measures.

Available from Mt. Sinai-Duarte National Medical Center, 208 West 8th St., Los Angeles 4.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Unto the Least of These—Social Services of Children—*By Emma Octavia Lundberg. New York: Appleton-Century, 1947. 424 pp. Price, \$3.75.*

This is a good source book for those deeply interested in the development of social services in this country, and also gives a general picture to those less oriented. The book should be of particular value to those who work in the public health services for children and do not have a clear idea of the function and operation of child welfare services. The book discusses social welfare and its history in this country and considers in some detail the problems of foster care, of delinquent and neglected children, and of public and private agency services for them. Historical and documentary material are scattered throughout the text. In the opinion of this reader, two chapters devoted to the contributions of various individuals seem to be inserted to not very good purpose in the middle of this story.

The author, who has long been associated with the child welfare work in the federal Children's Bureau, has approached different topics with varying degrees of understanding and breadth of vision. For example, in a discussion of care for foster children, we find this sentence:

Those of us who remember the bitter controversies, most of them academic and partisan, which raged two decades ago over the question of institutional *versus* family-home care know how futile was this discussion of methods of care, and how it bypassed the vital issue of the circumstances under which a child should be received for care by *either* institutions or child-placing agencies.

The broad approach that this point of view indicates to the foster care pro-

gram is, however, not apparent when day care for children is discussed. Here, consideration of the contributions made by research groups in child growth and development, by progressive nursery schools, etc., is almost entirely ignored. The problem is seen in the following terms:

Experience during the past few years has shown that the states and communities must assume public responsibility for the proper care and protection of children who are orphans for the day, and that proper provision for this form of care demands the combined efforts of agencies in the fields of social welfare, health, and education.

True, there is brief mention of the rôle which day care can perform "in the physical and mental development of young children," but there is no real consideration of the value of social and group experience for young children for the sake of the children themselves regardless of their "orphan state."

It is also of some interest that in the discussion of federal aid for services to children great emphasis, as is to be expected, is placed on child welfare services and some attention given to services for crippled children. The assistance given through maternal and child health funds available also through the Social Security Act is ignored. Actually, however, this cannot stand as a criticism of the author for, as one looks at child welfare services in general, he sees that they too follow the pattern which the author has presented.

LEONA BAUMGARTNER

Science and Public Policy—*Volume I. A Report to the President by John R. Steelman, Chairman, The President's Scientific Research Board.*

Washington: U. S. Government Printing Office, 1947. 71 pp. Price, \$.20.

This report, prepared by the President's Scientific Research Board, provides a valuable summary of present official and private resources in this country for scientific research and a suggested plan for the rapid expansion of those resources. Although until World War II we had never consciously defined our objectives or organized our resources for science, there had been a rapid growth in research expenditures, rising from \$166 million in 1930 to \$345 million in 1940. In order to meet the defense needs and economic requirements of the country the report strongly recommends that annual expenditures for research and development be increased as rapidly as facilities can be expanded and trained man power be increased. At the moment it is estimated that the total research funds available for the nation are about as high as they can effectively go in view of the limitations in trained man power and facilities. The report advocates, however, that the present research budget should be doubled by 1957 so that at the end of a ten year period at least one per cent of our national income shall be devoted to research and development in the universities, industry, and the government.

The drying up of scientific sources in Europe, the interruption of normal interchange of scientific knowledge and the over-emphasis during the war years on applied rather than basic research make it imperative that the federal government launch a comprehensive program of development without delay. In order to promote such a program effectively the Board recommends that a National Science Foundation be established with a director appointed by and responsible to the President. It is proposed that this Foundation should support basic research in the universities and nonprofit research institutions at

a progressively increasing rate, reaching an annual expenditure of at least \$250 million by 1957, for, as Sir Henry Dale pointed out in a recent address, "to concentrate almost the whole of a rapidly growing scientific effort on practical applications and developments, as happened during the war, would correspond to reckless cropping of land without care to nourish the soil." The Board further recommends that federal assistance to universities and colleges be developed in supplying laboratory facilities and scientific equipment as an integral part of a general program of aid to education. The program would also include scholarships and fellowships for students of the sciences.

Many other important aspects of a national scientific program which cannot be covered in a short review are discussed in the report. Anyone interested in the future of science in this nation will wish to study the report for himself with care.

HUGH H. SMITH

Medical Care and Costs in Relation to Family Income—By *Helen Hollingsworth, Margaret C. Klem, and Anna Mae Baney*. (2nd. ed.). (Bureau Memorandum No. 51) Washington, D. C.: Supt. of Documents, 1947. 349 pp. Price, \$1.25.

This is the second edition of a statistical source book on medical economics. It is a paper bound, 8 x 10 inch volume, published by offset printing, and contains 317 tables taken from various publications.

The sections added since the first edition contain 14 tables on the economic characteristics of the population and 21 on vital statistics. A 7 page table gives in detail the benefits included in each of 44 new industrial group insurance plans using commercial insurance companies.

This useful reference book should be on the shelves not only of all those interested in medical care and health in-

surance but of health departments, schools of public health, and community hospitals. It contains most of the statistical information commonly referred to.

Brief descriptions are given of 23 important studies from which tables are taken. These enable the reader to form his own conclusions as to value. A footnote under each table and an alphabetical list of 138 references gives the reader the sources of each of the tables.

The greatest value in this book is the newness of the material. Most of the tables are more recent than 1940 and a considerable number go beyond 1944. It is gratifying that this type of material is not only available but is being republished at reasonably frequent intervals.

V. L. ELLICOTT

Water Supply and Sewerage—By Ernest W. Steel. (2nd rev.) New York: McGraw-Hill, 1947. 666 pp. Price, \$6.00.

The author states that this book is an attempt to present for engineering students those essentials of principles and present-day practice necessary to solution of the problems of water supply and sewerage. The changes from the first edition (1938) are minor.

There are a number of details relating to developments in the past ten years which need correction by checking on current practice and reference to current literature. In some cases apparatus is described, without qualification, which has been more or less discarded since the first edition. The material on sludge treatment and sludge processing, as well as on handling garbage with sewage, needs revision.

The usefulness of the book would be enhanced by a concise bibliography of outstanding articles and books. Should a new edition be contemplated, the author would do well to submit the various parts of the book to practising engineers for correction and suggestion.

For health officers and others desirous of a general view of the field, the book should prove useful and informative.

LANGDON PEARSE

Food Poisoning—By Elliott B. Dewberry (2nd ed.). London: Leonard Hill, Ltd, 1947. 246 pp. Price, \$5.00.

This volume, which is a revision of the book first published in 1943, brings together voluminous information in regard to the varieties, causes, modes of transmission and control of the agents which cause food poisoning. It is a valuable handbook for both the field investigator and the laboratory worker. In such an exhaustive treatment of the subject, much technical information and phraseology must necessarily be included. This does not make it easy reading for persons lacking the necessary scientific background.

The book is attractively printed and well illustrated for one which has been issued during this period of shortage of paper and restrictions upon printing. One interesting feature is the inclusion of photographs of investigators who have contributed to our knowledge of food poisoning. This will be the first time that many persons will have seen the likeness of some of these individuals.

There is a very thorough discussion of salmonella infections carried by food, staphylococcus food poisoning and botulism. Those who read the book should realize that toxins produced by salmonella organisms have not been conclusively demonstrated and there is reason to believe that such supposed toxins may really have been produced by accompanying staphylococci rather than salmonella organisms.

The information regarding contamination of foods by poisonous metals and that in regard to poisonous plants makes a very useful check list of items to be considered when investigating outbreaks of illness due to foods. A well selected bibliography at the end of each chapter

makes it possible to explore further into both the historical papers and the more recent investigations.

ROY F. FEEMSTER

5,000,000 Casualties on the Home Front—By Louise Neuschutz. New York: Beechhurst Press, 1947. 184 pp. Price, \$3.50.

Correctly called a handbook of home safety, this volume gives evidence of a wide knowledge of the causes of accidents and impresses one with the author's sincere conviction that accidents can be stopped.

Mrs. Margaret Culkin Banning in a foreword calls upon the nation to wipe out accidents and expresses a belief that this book is a tool toward such action.

Physical and mental causes of accidents are touched upon, although the book leans quite heavily on the theme of carelessness, especially in accidents to children. Parents are given suggested reading.

In addition to the several chapters on home safety, chapters are included on farm safety, fire prevention, first aid, and safety for the physically handicapped.

Good type, attractive headings, chapter summaries and questionnaires, illustrations and an index, add to the readability and usefulness of the book. Case histories taken from newspaper accounts are liberally used.

Intended primarily for the home-maker, the book is of value to school teachers, public health nurses, health educators, and safety engineers. The author has the ability to arouse interest and to point out a job in accident control for every type of reader.

ETHEL M. HENDRIKSEN

Nursing—By Lulu K. Wulf. New York: D. Appleton Century, 1947, 534 pp. Price, \$3.50.

Miss Wulf's treatment of the subject, nursing, is on an unusually broad scale,

taking in nursing history, current trends and problems and then, under finer focus, nursing techniques and procedures. Her approach is fresh and typical, it is to be hoped, of all future textbooks which remind the student that the patient comes to the hospital from a home, usually as a member of a family and that he will return to a home, a place of work and to normal living in a community. Such headings as "Methods of reassuring the patient on admission to the hospital," "Interpreting hospital regulations regarding visitors," and "Helping the patient and his family plan for his care at home," are indicative of this richer point of view which widens the function of the hospital and of the nursing care given in it.

The descriptions of nursing techniques which occupy more than half of the book are simply expressed and clarified by effective illustrations. To an unusual degree they take into account the patient's reactions and his need of understanding what goes on around him.

The criticism which will be made by many readers is that in choosing a wide angle lens for her picture of nursing, Miss Wulf has necessarily had to omit many details, so that instructors will find many subjects, such as medications and diagnostic tests, only partially covered and frequently that which is given, duplicates the usual presentation in special textbooks. This reviewer, also takes exception to the order of subject matter which places today's developments in nursing at the beginning of the book, and closes it with "Preparing the patient for the morgue."

DOROTHY DEMING

Reading and Visual Fatigue—By Leonard Carmichael, Ph.D. and Walter F. Dearborn, M.D., Ph.D. Boston: Houghton Mifflin, 1947. 483 pp. Price, \$5.00.

In this monograph the authors present a subject which has previously been

characterized by confusion in an orderly and intelligible manner. The initial chapter provides a summary of fact and current speculation concerning the physiology and psychology of vision and the phenomena which are generally grouped together under the term "visual fatigue." The visual task of "reading" is analyzed, with special attention given to the problems presented by typical forms of the printed page. The extensive literature on "blink-rate" as an index of visual fatigue is tabulated and discussed. A logical doubt concerning the validity of this criterion is clearly stated.

The problem of illumination is not answered by any definite recommendations. The extensive but inconclusive investigations of the lighting engineers on the one hand and the biological scientists on the other are cited. The differences of these groups, which exist only in special cases and have proved to be more apparent than real, are somewhat overemphasized by the present authors. Unfortunately the fundamental work of H. C. Weston (Medical Research Council—London—*Industrial Health Research Board Report 87*) on the relation of illumination and visual efficiency is not considered.

The authors' own work, involving the optical recording of eye movement and the electrical evaluation of eye muscle activity, is described in detail. Visual fatigue is concluded to combine, in varying proportions, mental, physical and chronic fatigue. As fatigue develops it results in an alteration of the general attitude of the subject and characteristic changes in the reading pattern. Breakdown of the coordinated physiological mechanism made up by the sensory cells, the eye muscles and all the related nervous system cannot be demonstrated and direct evidence of physiological fatigue of the visual processes is evident only under the most abnormal conditions.

The authors have been very success-

ful in presenting the main facts and the important experimental work relating to the problem of visual fatigue in reading. The unsolved problems, listed in every chapter, give a valuable reminder of the tentative nature of all present conclusions in this field.

DONALD YOUNG SOLANDT

Problems of Early Infancy — *Transactions of the First Conference, March 3-4, 1947. New York: The Josiah Macy, Jr. Foundation, 1947. 69 pp. Price, \$.75.*

This publication is a record of the transactions of a conference sponsored by the Josiah Macy, Jr. Foundation and composed of a group of psychiatrists, psychologists, pediatricians, and educators interested in the emotional problems of early infancy. It was the consensus that emotional instability in children and mental disease have their origin during the early period of infancy and that the elimination of problems at that stage should provide a psychologically healthy adult. Comparisons of unique parent-infant relationships to mental disease rates of various races and nationalities are given as supportive evidence.

This group believed that in this country the greatest hazard to healthy emotional development is encountered during the lying-in period when the infant is subjected to routine hospital care, rigid feeding schedules, and separation from the mother. The "rooming-in" plan and "self-demand" schedule was enthusiastically proposed as a means of fostering a more healthy and natural parent-infant attitude and as a means of encouraging breast feeding.

There was considerable discussion concerning the most effective means of educating medical students, physicians, and the general public to this line of thought.

Very little or no objective data were presented in support of the proposal, which was more in the nature of an hy-

pothesis but which, after very careful trial and analysis, may prove to be helpful in the prevention of behavior disorders and mental disease.

RANDOLPH BATSON

Dr. Kirkbride and His Mental Hospital—By *Earl D. Bond, M.D.* Philadelphia: Lippincott, 1947. 162 pp. Price, \$3.50.

This little book is both a historical document and a reminder that "we are better scientists than Kirkbride and his friends, but not better people" for all the fact that a hundred years have passed since Kirkbride's Pennsylvania Hospital was opened. The biographic section paints the picture of Kirkbride's Quaker family living in the neighborhood of Philadelphia and of the education of a physician from 1820 to 1830. During Kirkbride's life, Philadelphia grew from a town of about 100,000 to a city eight or nine times that size. Dr. Bond sketches in with interesting anecdotes, though at times rather too briefly for the reader's satisfaction, the effect of this growth on the mental hospital and on Kirkbride.

Kirkbride's ideas on the treatment of patients in a setting of pleasant and safe buildings and grounds remain the ideal of hospitals for the mentally ill. His firm belief that "the best hospital—best built, best arranged and best managed—is always cheapest in the end," is particularly pertinent at this time of large scale hospital planning and construction and applies equally for the general as for the special hospital. His gentle and kindly attitude toward his patients was based on a sincere respect for them, a respect which it was easier for him to teach his attendants because he held it so sincerely. Kirkbride's conception of occupational therapy was hardly behind the best thought of 1947, and his accomplishment was far above that of most hospitals of the present time.

This is not an intimate type of biography. We see the man Kirkbride largely through his acts, not by interpretation of what his biographer conceived his thoughts and drives to have been. His hospital plans, the daily routines he set up, his formal relations with fellow physicians are recorded in a simple, artless style most pleasant to read.

PAUL V. LEMKAU

City Finances: 1945. Volume 1: Individual City Reports (For each city having a population over 250,000); **Volume 2: Topical Reports** (On debt and other selected topics); **Volume 3: Statistical Compendium** (Cities having populations over 25,000)—*Prepared under the supervision of Allen D. Manvel, Bureau of the Census. Washington, D. C.: U. S. Government Printing Office, 1947.* Price, \$1.25 each.

Here are statistical tables covering practically everything one might want, or at least could reasonably find out, about city finances. There are tables showing, city by city, expenditures for sanitation and for health and hospitals, as well as for other municipal functions.

MARTHA LUGINBUHL

Report of the Working Party on the Recruitment and Training of Nurses—*Prepared by Department of Health for Scotland, Ministry of Health, Scotland. London: His Majesty's Stationery Office, 1947.* 122 pp. Price, \$.75.

Those who are concerned with the basic problems of recruitment and training of nurses in North America will be interested in this *Report* representing a study of more than one year for the British Ministry of Health and the Department of Health for Scotland. The attempt was made to review the problems of nursing from a very broad point of view.

There are familiar phrases among the

conclusions such as, "Nurses in training must no longer be regarded as junior employees subject to an outworn system of discipline. They must be accorded full student status. . . ." "If student nurses were relieved of domestic work and of nursing duties dictated solely by the staffing demands of hospitals, a period of two years would suffice for a general training." "The period of two years would be based on a five-day training week of 40 hours and would allow for six weeks annual holiday." "The explicit aim of the new system would be the development of a nursing service in closer accord with modern ideas of social and preventive medicine. Health nursing and sick nursing must be considered side by side."

This is an illuminating discussion of how the problem is being faced in Great Britain. REGINALD M. ATWATER

On Hospitals—By S. S. Goldwater, M.D. New York: Macmillan, 1947. 395 pp. Price, \$9.00.

This volume will influence health-minded people of the future as much as Dr. Goldwater's dynamic personality stimulated those who were fortunate enough to know him personally. No other book can surpass it for sound philosophy, keen awareness of problems, and excellence of writing. One regrets only that *On Hospitals* does not tell us more about Dr. Goldwater as a man, a husband, and a father, as well as how his thinking led him to meet the opportunities of his time.

Every doctor, nurse, and person in public health should consider *On Hospitals* as a "must" to keep thinking in broad channels. JOHN E. GORRELL

Fungi—By Frederick A. Wolf and Frederick T. Wolf. New York: Wiley, 1947. Vol. I, 438 pp., price, \$6.00—Vol. II, 538 pp., price \$6.50.

This two volume treatise is intended as a reference and textbook. Volume I is devoted to a consideration of developmental morphology and taxonomy of fungi. Chapters 1 to 3 are devoted to a consideration of history, methods of isolation and cultivation, and classification and taxonomy. The remaining 5 chapters treat the specific classes. These chapters are unique in their presentation in that they stress the differential properties without going into the detail structural make-up of each species. They briefly point out the ecological and practical importance of these species.

The second volume, divided into 22 chapters, deals more specifically with the biology, chemistry, and activity of fungi, including pathogenicity for plants and animals. The two volumes bring together a wealth of factual data in this extensive field. In attempting to compress the essential knowledge concerning fungi into two small volumes it is to be expected that the treatment of each broad field must be sketchy. For example, the entire field of medical mycology is treated in chapter 16 of Volume II in 31 pages. *Coccidioides immitis* is discussed in 1 page with no reference to several noteworthy contributions of the past 3 years. Slightly over 1 page is devoted to *Histoplasma capsulatum*. Poisonous and edible fungi rate 25 pages, while soil fungi are allotted 16 pages. These figures are given to emphasize that the student of any special field will find little of value in his specific field. However, such was not the intent of these volumes. They do provide the basic information and do it exceptionally well. Both volumes are replete with references to which the authors repeatedly refer the reader for more detailed information in specific fields.

The numerous illustrations, many of which are original, are excellent. The discussions are lucid and the organiza-

tion of the material logical. In place of the usual summary at the end of each chapter, the authors have elected to use the term "implications." Any student of biology will find these well worth reading, even if he skips the rest of the volumes. The printing and binding are better than we have seen in a long time.

While these volumes will be found to be valuable reference books on the fundamentals of mycology for public health laboratories and workers specifically interested in mycology, they will find little use by other public health workers.

M. H. MERRILL

Dynamic Mental Hygiene—By Ernest and Catherine Groves. Harrisburg, Pa.: Stackpole Sons, 1946. 559 pp. Price, \$3.75.

This book is a very detailed exposition of mental hygiene as seen by two devoted workers who have spent their lives as non-medical counselors in the field of personality interactions. It is divided into two sections, the first tracing the mental hygiene implications of various scientific and professional disciplines, including the general field of medicine and the specialty of psychiatry along with biology, psychology, education, sociology, social work, the law, and finally, the ministry. In this section there is also a chapter on the home and its mental hygiene implications. The second section deals with the application of mental hygiene principles in family counseling, the area of the authors' particular interest.

The definition of mental hygiene exemplified in this book implies a vast range of knowledge on the part of the specialist in the field, as indicated in the table of contents. For the most part, the Groveses have this knowledge and it is coupled with good common sense in most instances. That such knowledge can be present in people of lesser endowment who are in service rather than academic positions is, however, ex-

tremely doubtful. This book is prepared, apparently, for use as a textbook, though at what educational level is unclear. It is extremely doubtful that it could be used to advantage below the level of the Ph.D. candidate, since it involves such a tremendous background of knowledge that those of less education would find it so far beyond them it would be useless. There is less of the material of personality development than might be expected in so thorough a treatise.

The attitude toward medicine reflects the non-medical background of the authors. Medicine is conceived as having primarily the function of ruling out or ruling in the presence of organic disease. The interrelation of the emotional life of the patient and his disease is freely granted, but the problem of therapy of the patient and his disease is considered to be primarily non-medical. ". . . some doctors have, more or less willingly as their individual preferences dictated, become mental hygiene counsellors as well as physicians" (p. 78). The psychiatrist is likewise considered to be one who confines his attention to the mentally ill, and to have mental hygiene only as a secondary interest. This attitude toward physicians probably is the result of long experience which has found them useful only in the ways stated; it should prove a challenge to those who feel that the medical student should be educated so that his medical view includes the personality functions of his patient.

The book is printed on very shiny paper which constantly gives extremely bothersome highlights that interfere with the reading. It is poor ophthalmologic hygiene to read it, a matter the publisher might well give attention to in future printing. PAUL V. LEMKAU

An Approach to Social Medicine—By John D. Kershaw, M.D., D.P.H. Baltimore: Williams & Wilkins, 1946, 329 pp. Price, \$4.50.

Dr. Kershaw, a British Medical Officer of Health, has formulated an approach to social medicine that will surprise most public health readers in this country. It is a philosophical account of the social functions of medicine which hardly mentions health insurance or group practice, makes only passing comment on problems like the distribution of medical personnel and facilities, or the incidence of illness in different population groups, and offers no discussion on the administration of various programs of medical care.

Instead, this comprehensive volume takes a truly Aristotelian view of social medicine, a view so broad that strict preventive or therapeutic services, as we usually understand them, play only a minor part. Rather it is the fundamentals of community organization, economic relationships, law, social psychology, and such subjects that comprise Dr. Kershaw's sweeping analysis of the "anatomy," "physiology," and "disorders" of society. The discussion

of "health and sickness in society" deals briefly with some of the ethical and humanistic problems of surgery, obstetrics, industrial hygiene, communicable disease control, and other special fields. Fuller discussion is offered on the significance in the healthful life of food, housing, work, leisure, sex, genetics, and education.

This study can probably be best described as a general social critique, written rather incidentally by a physician. It is mindful in some ways of the sociological writings of Edward Bellamy or Lester Ward, with all social functions described somewhat mechanistically as adjusted to social needs, though recommendations for improvement are offered. The entire concept of social medicine is under active discussion today. It is likely that American definitions of the field will be somewhat more restricted, but Dr. Kershaw's broad-gauge view provides valuable perspective against which our approach can be hammered out.

MILTON I. ROEMER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Last Word Department—In summary form, the nutritional advantages of breast milk and the emotional advantages of breast feeding are discussed, together with objections and contraindications. The statement carries top-notch approval.

ALDRICH, C. A., *et al.* The Advisability of Breast Feeding. J.A.M.A. 135, 14:915 (Dec. 6), 1947.

You Buy Health—Possibly you will not be surprised by the findings of this study—that total death, infant and maternal mortality rates, as well as death rates from certain diseases vary inversely with family income status—but

you should know about it for you will want to preserve the paper for ammunition in case you find yourself in a medico-economic argument some day.

ALTENDERFER, M. E. Relationship between per Capita Income and Mortality, in the Cities of 100,000 or More Population. Pub. Health Rep. 62, 48:1681 (Nov. 28), 1947.

British Health Services—Everyone who has access to the publication should make a practice of reading the "Letter from Britain" section of the *Canadian Public Health Journal*. These little essays reveal the adult frame of mind with which your conservative Briton perceives the encroachments of socializa-

tion, making the best of what must seem to him a pretty dubious bargain. Wouldn't it be wholesome if some of our bad-name-calling protagonists could catch a little of this infectious emotional maturity?

BROCKINGTON, F. Letter from Britain. *Canad. Pub. Health J.* 38, 11:552 (Nov.), 1947.

Stopping Epidemic Diarrheas—

In the last decade a revolutionary change has come about concerning childbirth. Ten years ago there were many home deliveries: now there are almost none. There can be but one answer to this phenomenon, asserts the writer. People are convinced that the hospital is the safest place for a mother to have a baby. Safest for the mother, it is; but is it safest for the baby? Improvements are proposed to make hospitals safer for new-borns.

CLIFFORD, S. H. Diarrhea of the Newborn. *New England J. Med.* 237, 26:970 (Dec. 25), 1947.

"Easier To Read Than Skip"—

If you never write anything but duty letters to your dear old mother then you may safely ignore this item. Otherwise you should know about the pains the Extension Service takes to make its educational material readable. Also, this note gives me the chance to add to hers, my boost for Flesch's "Art of Plain Talk," a book you need to read once each year.

COWING, A. G. Readable Writing. *J. Am. Diet. Assn.* 23, 12:1036 (Dec.), 1947.

Newly Discovered TB—Expanding diagnostic and treatment facilities for tuberculosis serve to make the shortage of nurses a bottleneck (if I may resurrect a tired word). One solution is the employment of non-professional workers to take over the chores the nurse shouldn't have to do. There are other solutions discussed here.

CHRISTENSEN, H. G. and BOWE, A. Current

Trends in Tuberculosis Nursing. *Pub. Health Nurs.* 39, 12:590 (Dec.), 1947.

More about the Histoplasmin Monkey Wrench—Widespread pulmonary lesions caused by other agents than Tb and occurring especially in Tennessee, Kentucky, Arkansas, Missouri, Kansas, Illinois, Indiana, and Ohio complicate the problem of mass chest x-raying. Photographs are appended to show typical pictures of patients who are histoplasmin-sensitive and tuberculin-negative.

FURCOLOW, M. L., *et al.* The Roentgenographic Appearance of Persistent Pulmonary Infiltrates Associated with Sensitivity to Histoplasmin. *Pub. Health Rep.* 62, 49:1711 (Dec. 5), 1947.

Polio Studies—Relative epidemiologic importance of virus in stools and in the throat remains to be ascertained, say these researchers, but the fact that stools may remain infective for weeks whereas the infectious period seems usually to end a few days after onset suggests that the source is *contact* infection and not via feces.

GORDON, F. B., *et al.* Recovery of Polio-myelitis Virus from Throat During the Incubation Period. *J.A.M.A.* 135, 14:884 (Dec. 6), 1947.

Extra Dividends—In cancer detection clinics conducted in Maryland the prevalence rates were ten times the expected rates for men and twice the expectancy for women. This experience seems to suggest that we should have more detection centers, for one thing. Preceding this story of the detection clinics is the introductory chapter of what will become a book on the diagnosis and treatment of cancer. Don't fail to look it over.

JONES, H. W. JR., and CAMERON, W. R. Case-Finding Factors in Cancer Detection Centers. *J.A.M.A.* 135, 15:964 (Dec. 13), 1947.

Quote—Today we are beginning to realize that although arthritis is not

communicable as a disease, its sociologic, economic, and public health implications are fully as serious. Unquote. You shouldn't need more to be convinced that this excellent paper is for you.

MARGOLIS, H. M. Rheumatoid Arthritis. *Am. J. Nurs.* 47, 112:787 (Dec.), 1947.

It will Not Stop—Of interest to every administrator should be this story of a year's experience in providing home care for the chronically ill. Essential to success was the close collaboration of all the agencies and professional groups concerned.

NOTTER, L. E. Coördinating Home Care for Persons with Long-Term Illness. *Pub. Health Nurs.* 39, 12:602 (Dec.), 1947.

Not on Dust—Oiling floors and treating blankets with oil emulsion lowers dust content of air. From past studies good effects in preventing bacteria-caused respiratory diseases have been reported, but the spread of virus infections seems not to have been affected markedly in this investigation.

SCHUCHMEISTER, I. L., and GREENSPAN, F. S. The Relation of Oil Treatment of Floors and Bedding to the Control of Respiratory Diseases among Naval Personnel. *Am. J. Hyg.* 46, 3:376 (Nov.), 1947.

Quotes from Immortal Bard—"What a piece of work is man, how noble in reason, how infinite in faculties.

In form and moving how express and admirable, in apprehension how like a god. The beauty of the world, the paragon of animals." With tongue-in-cheek a British M.O.H. begins his discussion of psycho-somatic disease with those words.

STALLYBRASS, C. O. The Social Implications of Medico-psychological Disorders. *M. Officer.* 78, 20:213 (Nov. 15), 1947.

In a British San—Pregnant tuberculous patients were compared with a similar group of married tuberculous patients, who were not pregnant. There was little or no evidence that childbearing had any effect on the course of the disease, and none that surgical interference was needed.

STEWART, C. J. and SIMMONDS, F. A. H. Child-Bearing and Pulmonary Tuberculosis. *Brit. M. J.* 4531:726 (Nov. 8), 1947.

Lo, the Poor Indian—Probably this is of little interest to you, but the report says the Navajo Indians have practically no preventive medical services and no sanitary protection. The reservation is alleged to be a dangerous reservoir of communicable diseases (especially tuberculosis) for nearby states.

WOODS, O. T. Health among the Navajo Indians. *J.A.M.A.* 135, 15:981 (Dec. 13), 1947.

ASSOCIATION NEWS

76TH ANNUAL MEETING

BOSTON, MASS., NOVEMBER 8-12, 1948

Members of the Association are already asking about hotel rooms in Boston.

On or about April 1, a hotel reservation application form will be mailed to every member and the Housing Bureau in Boston will operate on and after that date. The *Journal* will also quote hotel rates beginning with the April number.

ASSOCIATION COMMITTEE ON CHILD HEALTH

The officers and Section Councils of five of the Association Sections—Maternal and Child Health, School Health, Health Officers, Public Health Nursing, and Health Education—have unanimously approved a plan for an Association Committee on Child Health. This plan was formulated by the Executive Board at the Annual Meeting in Atlantic City on the basis of a report from Martha M. Eliot, M.D., President, and Hugh R. Leavell, M.D., a member of the Board, growing out of conversations with representatives of the Maternal and Child Health and School Health Sections.

The plan indicates the following purpose for the new committee:

To consider matters related to the health and medical care of children and to maternity care and to act for the American Public Health Association in its relations with national organizations and agencies, professional or nonprofessional, that are concerned with the advancement of child health, having due regard for the work of the Sections and of other committees of the Association. This would include the development of recommended standards, procedures and policies and development of relationships with such organizations as the American Academy of Pediatrics, the Federation of Obstetrical Associations, the American Medical Association, the National Education Association, the American School Health Association, and the National Congress of Parents and Teachers.

It further suggests the following duties:

1. Develop statements of principles and policies, content of program, and standards of performance in the maternal and child health field for the guidance of the Association;

2. Consider and make recommendations concerning undergraduate and graduate education for professional and technical workers in the maternal and child health field;

3. Consider research or investigations that are required to provide information on administrative, organizational and program matters necessary for the improvement of child health; and,

4. Act on matters related.

The plan recommends that funds be sought to provide the committee with a staff, including a physician competent to develop the work of the committee, clerical assistance, and such other professional consultants as may be needed, and to provide for other costs of the committee.

The following committee has been appointed by the Executive Board:

Leona Baumgartner, M.D., *Chairman*, Director, Bureau of Child Hygiene, New York City Department of Health.

Margaret Adams, R.N., Instructor in Nursing Education, Teachers College, Columbia University.

Allan M. Butler, M.D., Massachusetts General Hospital, Boston.

Richard F. Boyd, M.D., Director, Local Health Administration, Illinois State Health Department.

Edwin F. Daily, M.D., Director, Division of Health Services, U. S. Children's Bureau.

Mayhew Derryberry, Ph.D., Chief, Health Education and Training, U. S. Public Health Service.

Paul Harper, M.D., Associate Professor, Department of Public Health Administration,

Johns Hopkins School of Hygiene and Public Health.

Herbert R. Kobes, M.D., Director, Division of Services for Crippled Children, University of Illinois.

Frank Stafford, M.S., Specialist for Health Instruction, Physical Education and Athletics, U. S. Office of Education.

Frederick J. Stare, M.D., Associate Professor, Head of Department of Nutrition, Harvard School of Public Health.

Myron Wegman, M.D., Professor and Director, Department of Pediatrics, Louisiana State University School of Medicine.

J. M. Wisan, D.D.S., American Dental Association.

Kent A. Zimmerman, M.D., Consultant in Mental Health, California State Department of Public Health.

PHOTOGRAPH OF MILK SEDIMENT STANDARDS AVAILABLE

With the acceptance of the Off-Bottom Method of determining sediment in a can of milk, the need became apparent for a set of sediment standards based upon a definite weight of sediment and prepared from a recognized standard sediment mixture. The use of such standards guarantees that both the milk industry and the respective regulatory agencies will have a common reproducible standard for the grading of milk on the basis of its sediment content.

The standard sediment mixture consists of screened, oven-dried cow manure, garden soil, and charcoal, mixed in definite proportions. Measured quantities of the sediment are added to a pint of milk before filtration through sediment discs. The photograph represents the amount of sediment remaining on the discs after filtration of pint samples containing 0.0, 0.2, 0.5, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, and 14.0 mg. of the standard mixture.

From the photograph, both the industry and the respective regulatory agencies may determine the limit in terms of milligrams of sediment beyond which milk will not be acceptable. Acceptable

limits may be established both for producer deliveries and for retail deliveries. Either actual discs or the photograph may be used in the field or in the laboratory for the purpose of making comparisons. The use of a photograph assures a high degree of uniformity.

Photographs of the discs are available at \$1.50 each from the American Public Health Association, 1790 Broadway, New York 19, N. Y. In order to protect the photographs from damage and fading, they are enclosed in acetate and manila envelopes. Directions for the preparation and use of the standards appear in the forthcoming ninth edition of *Standard Methods for the Examination of Dairy Products*.

NOTICE TO BIOLOGISTS INTERESTED IN PUBLIC HEALTH

Interest in the formation of a Public Health Biology Section of the American Public Health Association has been expressed by individuals whose major fields of interest and activity involve the application of biological knowledge and techniques to public health practice. These fields include medical or public health entomology, parasitology, mamalogy, limnology, ichthyology, malacology, herpetology, mycology, allergenic botany, and doubtless other related specialties. Existing Association Sections—mainly Laboratory, Epidemiology, and Engineering—provide proper affiliation for certain of the A.P.H.A. biologists; it is not proposed that any of these currently satisfactory relations be disturbed. Other biologists with investigational or operational concerns find themselves in the Unaffiliated Section for lack of an Association category indicative of their professional interest. It is believed that some public health biologists have failed to join the American Public Health Association because there appears to be no specific place for them within the existing compartmentalization of the society.

A petition for the formation of such a Section in the Southern Branch of the A.P.H.A. has already been sent to the Governing Council of that organization. It seems desirable, however, to measure interest in the activation of a comparable Section on a national basis to provide the opportunity at the annual meetings of the A.P.H.A. for the presentation of more detailed papers and technical discussion of mutual problems in public health biology than might be

undertaken in the general sessions of the Association.

As a preliminary step in this direction, it is requested that those interested in the formation of a Public Health Biology Section in the American Public Health Association indicate their approval of such a plan and their willingness to cooperate in its activation by writing to Justin M. Andrews, Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Athemas Bellerive, M.D., 311 Glenn Ave., Ann Arbor, Mich., Director, Malaria Control Section, Public Health Service of Haiti
Joseph H. Gamet, M.D., Court House, Janesville, Wis., Medical Director, Rock County Sanitary Unit
Seth M. Kerron, M.D., 1949 Main St., Klamath Falls, Ore., Director, Klamath County Health Dept.
Norbert A. Lasher, D.V.M., Station Hospital, Randolph Field, Tex., Medical Inspector, U. S. Army
Albert M. Richmond, M.D., M.P.H., Hdq. 3rd Army, Medical Section, Atlanta 3, Ga., Chief of Preventive Medicine and Commanding Officer, 3rd Army Area Laboratory.
Harry P. Ross, M.D., 220 South 19th St., Richmond, Ind., City Health Commissioner

Laboratory Section

Alice J. Arnold, 191 N. El Molino Ave., Pasadena, Calif., Bacteriologist, City Health Dept.
Frank R. Bozza, Ph.G., 56 Sinawoy Road, Cos Cob, Conn., Bacteriologist, Greenwich Health Dept.
H. Gilbert Crecelius, Ph.D., 1010 Orleans, Topeka, Kan., Asst. Director, Division of Public Health Laboratories, State Board of Health
Carroll E. Heist, M.S., Dept. of Bact., Univ. of Illinois, Urbana, Ill., Student
Nicholas A. Milone, State Dept. of Health, 35 Market St., Poughkeepsie, N. Y. District Sanitarian
Lucille K. Schulze, 4954 West Pine Blvd., St.

Louis 8, Mo., Senior Asst. Bacteriologist, St. Louis Health Division
Gyudell L. Schwartz, M.A., 618 Elmwood Ave., Joliet, Ill., Chief Laboratory Technician, Hilo Memorial Hospital, Hilo, Hawaii

Vital Statistics Section

Robert Lewis, 228 MacArthur Blvd., Oakland 10, Calif., Student of Public Health Statistics, Univ. of California.
Eleanor Poland, Ph.D., 2000 F. St., N.W., Washington, D. C., Special Consultant, U. S. Public Health Service
Matthew Taback, A.M., State Dept. of Health, 28 Howard St., Albany 7, N. Y., Senior Statistician, Division of Tuberculosis

Engineering Section

Robert V. Barnes, M.S.E., State Health Dept., 519 Dexter Ave., Montgomery, Ala., Principal Sanitary and Public Health Engineer
Walter M. Basford, M.A., Station Hospital, Randolph Field, Tex., Post Sanitary Engineer
Jose Capocchi, 615 Monroe, Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health
Philip Dreifuss, Box 2305 University Station, Gainesville, Fla., Student, Univ. of Florida
Hoke J. Duncan, P. O. Box 374, Dalton, Ga., Sanitarian, Dalton-Whitfield County Health Dept.
Warren R. Lawson, M.P.H., State Health Dept., University Campus, Minneapolis 14, Minn., Asst. Public Health Engineer
Lee J. Schreiber, 1705 Jancey St., Pittsburgh, Pa., Student, Univ. of Michigan School of Public Health

Henry L. Schuldener, 423 W. 126th St., New York 27, N. Y., President and Technical Director, Water Service Laboratories, Inc.
 Robert B. White, C.E., 222 Tyler House, East Quad, Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health

Industrial Hygiene Section

Marcelo Ernesto Auguste, M.D., 203 North Ingalls St., Ann Arbor, Mich., Physician, Medical Dept., Standard Oil Co. (Argentina)
 P. Cartier, M.D., D.P.H., Thetford Industrial Clinic, Inc., Thetford Mines, Que., Canada, Medical Director
 Comdr. Clark P. Jeffers, M.C., USN, Staff, Comdr. in Chief, Pacific Fleet, FPO, San Francisco, Calif., Medical Officer for Preventive Medicine and Asst. Fleet Surgeon
 Edwin M. Joseph, 1240 Ontario St., Cleveland, Ohio, General Manager, "Occupational Hazards"
 Jacques C. Presner, M.D., C.M., 30 West 54th St., New York 19, N. Y., Visiting Physician, City Dept. of Welfare
 Capt. Ivan C. Tiholiz, M.C., 19D McCann St., Edgewood, Md., Industrial Toxicologist, Army Industrial Hygiene Laboratory

Food and Nutrition Section

Cefairl W. Carlson, 623 N. Humphrey, Oak Park, Ill., Sanitarian, City of Oak Park
 Dale D. Chow, D.D.S., 769 Jackson St., San Francisco, Calif., Instructor in Anatomy, Univ. of California College of Dentistry
 Penelope S. Easton, West Lodge Dorm. 2, Ypsilanti, Mich., Student, Univ. of Michigan School of Public Health
 Luther A. Kohr, 1265 Broadway, Rm. 806, New York 1, N. Y., Exec. Secy., American Association of Medical Milk Commissions, Inc.
 Milton E. Lindemann, 230 South Park St., Fairmont, Minn., Sanitarian, Fairmont Canning Co.
 Elsie W. Russell, 1824 Geddes Ave., Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health

Maternal and Child Health Section

Harold M. Goldstein, M.D., 1282 East 23 St., Brooklyn, N. Y., Resident Pediatrician, Mount Sinai Hospital
 M. Alexander Novey, M.D., City Health Dept., Rm. 700, Municipal Bldg., Baltimore 2, Md., Director, Bureau of Maternity and Child Hygiene
 Deogracias J. Tablan, M.D., 1930 Washtenaw, Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health

Antonio H. V. Valente, 1312 Olivia St., Ann Arbor, Mich., Student, Univ. of Michigan School of Public Health
 Frank W. Van Dyke, 47 Melrose Ave., Albany, N. Y., Consultant on Administrative Methods, U. S. Children's Bureau

Public Health Education Section

Edna Y. Bond, 15 East Kinney St., Newark 2, N. J., Health Education Director, New Jersey Tuberculosis League
 Mary T. Connelly, 10 Chestnut St., Quincy, Mass., Health Educator, Norfolk County Health Assn.
 Enoch O. Dugas, 431 S. Broadway, Tyler, Tex., State Representative, National Foundation for Infantile Paralysis, Inc.
 John K. Ellis, West Lodge Dorm. 19, Rm. 85, Ypsilanti, Mich., Student, Univ. of Michigan School of Public Health
 Elmer L. Guenther, 1535 Summit Ave., Seattle 22, Wash., Secretary, Health Division, Council of Social Agencies
 Judson Hardy, 214 Monroe, Rockville, Md., Chief, Office of Technical Services, Venereal Disease Division, U. S. Public Health Service
 Dorothy Y. Kirk, M.P.H., R.N., 29 Wood St., Hamden, Conn., Nurse Supervisor and Assistant in Administration, Bureau of Venereal Diseases, New Haven Health Dept.
 Karl P. Meister, D.D., 740 Rush St., Rm. 510, Chicago 11, Ill., Exec. Secy. Board of Hospitals and Homes of Methodist Church
 Helen de Ramus Mitchell, 1278 Grant Ave., Bronx 56, N. Y., Asst. in Health Education, Westchester-Pelham Health Center
 Lily E. Orth, 12 South Oxford St., Brooklyn, N. Y., Supervisor, Out-Patient Service, Cumberland Hospital
 Elizabeth T. Pearson, County Court House, El Centro, Calif., Exec. Secy., Imperial County Tuberculosis and Health Assn.
 Ellaleen C. Williams, R.N., M.S., 458 H. St., S.W., Washington 4, D. C., Psychiatric Social Worker, St. Elizabeths Hospital

Public Health Nursing Section

Margaret E. Bernard, Box 261, Garden City, N. Y., Unemployed (formerly Public Health Nurse, State of California)
 Laura M. Brooks, R.N., Fair St., Carmel, N. Y., Public Health Nurse, District Nursing Assn.
 Madolin M. Dickinson, R.N., B.S., 929 Forest, Denver, Colo., Public Health Nurse, Denver Tuberculosis Society
 Dorothy G. Erickson, 4884 MacArthur Blvd., N. W., Washington 7, D. C., Asst. Nurse Officer, U. S. Public Health Service

Mary E. Lewis, R.N., 720 Church St., Trenton, Tenn., Acting Senior Public Health Nurse, Gibson County Health Dept.

Erna E. Maas, R.N., 52 Harrison Ave., Roseland, N. J., Public Health Nurse, Bloomfield Health Dept.

Rosemary M. MacIsaacs, R.N., 97 Border St., Cohasset, Mass., Unemployed (formerly Public Health Nurse, Social Service League)

Dorothea F. Miller, R.N., B.S., Rt. 3, Box 319A, Bremerton, Wash., Public Health Nurse, Kitsap County Health Dept.

Clara Rechtschaffer, R.N., B.S., 310 West 97 St., New York, N. Y., Field Supervising Nurse, City Health Dept.

Reva Rubin, M.N., Frontier Nursing Service, Brutus, Ky., Resident District Nurse and Nurse Midwife

Marjorie E. Schlotterbeck, 47 Beaver St., New York 4, N. Y., Nursing Consultant, American Cancer Society

Mabel A. Wandelt, 1110 Calvert, Detroit 2, Mich., Student, Univ. of Michigan School of Public Health

Epidemiology Section

Byron D. Casteel, M.D., 1840 Monroe Street, N. W., Washington 10, D. C., Officer-in-Charge, Communicable Disease Control Section, Bureau of Medicine and Surgery, Navy Dept.

Alfred E. Fischer, M.D., 73 East 90 St., New York 28, N. Y., Pediatrician

Prof. Gunnar A. Fischer, Statens Institut for Folkhalsan, Tomtebodavägen, Sweden, Professor of Hygiene, Royal Carolinian Institute

O. Elliott Ursin, M.D., 55 Shattuck St., Boston, Mass., Student, Harvard School of Public Health

School Health Section

Sidney Blumenthal, M.D., 1097 Park Ave., New York, N. Y., Pediatrician

H. Veazie Markham, M.D., 6095 Cerritos Ave., Long Beach 5, Calif., School Physi-

cian, Redondo Union High School and Torrance City Schools

Margaret H. Moore, M.D., 584 Copley Road, Akron, Ohio, School Physician, Summit County Health Dept.

Dental Health Section

Sylvia E. Zappler, D.D.S., M.D., 33 Davis Ave., White Plains, N. Y., Dentist

Unaffiliated

Bennett F. Avery, M.D., M.S., American Embassy, Tehran, Iran, Advisor to Imperial Iranian Ministry of Health

L. Whittington Gorham, M.D., Albany Hospital, New Scotland Ave., Albany 1, N. Y., Chairman, New York State Public Health Council

Joseph F. Poges, Box 230, Springfield College, Springfield, Mass., Student in Health Education

Donald B. Seeley, M.S., Flint Laboratory, Univ. of Massachusetts, Amherst, Mass., Student

DECEASED MEMBERS

W. M. Brien, M. D., Orange N. J., Elected Member 1935, Health Officers Section

Hyman M. Charm, Sc.D., Bronx, N. Y., Elected Member 1937, Laboratory Section

Mrs. Sigrid M. Dudley, Marinette, Wis., Elected Member 1930, School Health Section

Joseph P. Franklin, M.D., Cumberland, Md., Elected Member 1946, Health Officers Section

Sara Kerr, Buffalo, N. Y., Elected Member 1935, Vital Statistics Section

Kingsley Roberts, M.D., New York, N. Y., Elected Member 1939, Unaffiliated

Wellington P. Shahan, Springfield, Ill., Elected Member 1941, Public Health Education Section

Herbert F. True, M.D., Sacramento, Calif., Elected Member 1926, Elected Fellow 1930, Health Officers Section

Kenneth M. Wheeler, Ph.D., Hartford, Conn., Elected Member 1940, Elected Fellow 1943, Laboratory Section

EMPLOYMENT SERVICE

Write Box V-1, Employment Service. A.P.H.A.

Position in School Health Education or public health education wanted by woman with many years' experience in teaching and community organization in public health. Master's degree in public health. East or Middle West preferred. Write Box H-E-1, Employment Service. A.P.H.A.

Biological and Physical Chemist available for research, control, teaching. Extensive experience research, industrial development and control on pharmaceuticals, biologicals, bio-assays, also expert in animal surgery. Original analytical and physical-chemical methods. Former University professor, 60 publications; many in medical research; books. Executive ability. Age 35, married, children. Seeks responsible position Hospital Laboratories or Educational Institution, New York Metropolitan area preferred. Box L-2, Employment Service. A.P.H.A.

Sanitary Engineer, A.B., M.S., C.E., 3 years' experience in Public Health Engineering with Federal, State, and local agencies. Army experience in water supply in the Pacific. Desires position in public health engineering. Write Box E-1, Employment Service. A.P.H.A.

Health Educator, B.S. in Education, New York University, M.P.H., Yale University Department of Public Health. Experienced in community organization with City Health Department; Instructor of Health Education in University. Interested in Health Education in the community or as School Health Coördinator. Write Box H.E.-2, Employment Service. A.P.H.A.

Graduate Veterinarian with undergraduate and graduate work in dairy technology, experienced in both fields, desires position as sanitarian in a public health capacity or related work; suggestions solicited. Write Box V-2, Employment Service. A.P.H.A.

*Advertisement***Opportunities Available**

WANTED—(a) Health educator to serve as consultant to educators in state health department; Master's degree in public health and three years' experience required; \$4,000-\$4,800. (b) Graduate engineer with major in sanitary or public health engineering; to join staff of large industrial company having operations in Latin America; duties consist of directing sanitary program in two or three districts; work of non-routine nature. (c) Public health engineer; municipal health department; Rocky Mountain state. (d) Sanitary engineer to direct department serving population of 7,000,000; experience in water and malarial control required; M.A. degree and public health background essential; South America. (e) Public health statistician and, also, health educator; county department of health; southern California. (f) Health educator; city health department; university medical center, Middle West; around \$4,000. **PH2-1.** Please write to Berneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

WANTED—(a) Public health officer; Korea; \$6,000, traveling expenses. (b) Public health officer; degree in public health and experience in rural health desirable; administrative position; headquarters in one of the leading cities of South America; \$7,200. (c) Public health officer to administer program of two counties; combined population 50,000, principally agricultural in nature; well staffed department; Middle West. (d) Student health physician to direct department, eastern university. (e) Medical director and

administrator, health service; duties consist of directing health program, serving as consultant and adviser to other departments such as nursing, nutrition, and safety service; \$6,108-\$7,968; university medical center of Middle West. (f) Public health physician experienced in administration for assignment in Greece. (g) Student health physician, man or woman; faculty rank of assistant professor; Pacific Coast. **PH2-2.** Please write to Berneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

WANTED—(a) Advisory nurse for generalized program; duties consist of supervising local agencies throughout state, \$3,600-4,300. (b) Public health nurse faculty members, interested in university teaching; ranks: assistant professorships; 10 month year; \$4,000-\$5,000. (c) Public health supervisors and staff nurses for positions in South America; knowledge of Spanish or Portuguese desirable. (d) Pediatric and orthopedic nursing consultants; state crippled children's department; program being reorganized; considerable traveling. (e) Public health nurse for administrative position in Korea; \$5,000, traveling expenses. (f) Outpatient supervisor; teaching clinic averaging 100,000 visits annually, affiliated with medical school and hospital; \$3,000-\$5,000; East. (g) Public health supervisor to direct generalized public health nursing and school health program; should be qualified to develop service; ample assistance; town of 85,000; minimum \$3,600-\$4,000. California. **PH2-3.** Please write to Berneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

*Advertisement***Opportunities Wanted**

PUBLIC HEALTH NURSE is available for administrative position; B.S. in public health nursing; Columbia University; M.A. degree in health education; in addition to several years' successful teaching experience, has served for five years in administrative capacity with state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

SANITARIAN; B.S. degree in Civil Engineering; six years, maintenance engineer with large institution; seven years, sanitary engineer where assignments have included insect control and general environmental sanitation; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

HEALTH EDUCATOR; B.S., M.A. degrees, eastern universities; several years, director of physical education in public schools; four years, health educator,

nationally known organization; three years, health educator in industry; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

INDUSTRIAL HYGIENIST; Ph.D. degree; several years, instructor of industrial hygiene and bacteriology, graduate school of eastern university; past two years, industrial hygienist of large industrial company; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

PUBLIC HEALTH PHYSICIAN seeks directorship; medical degree, eastern university; M.P.H. Johns Hopkins; 17 years' experience in public health field; during the war held important assignment abroad; now director of health, city of 100,000; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

WHERE WE ARE ON FOOD

The Food and Nutrition Board of the National Research Council, believing it had an obligation to help the people of the United States understand the world food situation, in November, 1947, prepared what it considered dependable conclusions based on facts available. These have been published in an 11 page mimeographed statement summarized below.

The recovery of the food situation in Europe has been slowed because of soil depletion, lack of fertilizer, due primarily to lack of coal for nitrate plants, which in turn is due in part to lack of adequate food to sustain productive capacity among coal miners, and in part to loss of livestock and consequent depletion of natural manure fertilizer; to the extreme cold of last winter which froze much winter wheat, and to the drought of last summer which resulted in a poor cereal crop and reduced pasturage. At the moment, lack of feed is sending light weight animals to market and thus temporarily providing more meat but making for severe shortage both in meat and breeding animals later. For another 2 or 3 years, Europe must rely chiefly on food rather than feed crops to sustain its population.

As to the disputed question of whether there is underfeeding, malnutrition or starvation in European countries, the report divides the problem into four groups: the well-to-do who can usually supplement rationed foods with unrationed, and thus have maintained good nutritional status; working classes in the cities whose diets have been good enough to keep most of them in good health but without enough calories to enable them to perform the full quota of the heavier kinds of work, thus giv-

ing the uninitiated observer the impression that they lack ambition rather than nourishment, especially if the observer does not also see the evidence of underfeeding in the workers' growing children; the farm population who are generally better fed than urban dwellers, except in areas of extreme soil depletion, loss of equipment, or displacement of families, conditions probably most severe in Greece, Italy, and Poland; and low income urban groups among whom many families have been underfed ever since the war and often even before the war because there is no breadwinner, their income is insufficient to buy their rations or the rationing system has broken down and they are unable to buy food in the black market. This group may be as high as a third of the families in some cities and among them there are not only evidences of underfeeding but often high mortality rates.

The report discusses also the ability and the responsibility of the United States in the situation. Europe must cut down its use of breadstuffs 75 grams or 3 slices of bread daily unless cereal imports can be increased by 280,000 bushels. Such a cut would be serious in countries where meats, oils, fats, dairy products, and eggs are far below pre-war levels.

The United States can save wheat and other cereals substantially only by reducing amounts fed to livestock and poultry. Meat is the most expensive form of calorie and protein production. An average acre of wheat, if consumed as bread, will provide 6 times as many calories as if fed to poultry and consumed as eggs, 8 times as many as if fed to broilers, and 19 times as many as if fed to beef cattle to fatten them after they leave the ranges. The most

following questions about cardiac rehabilitation:

- a. Work tolerance of various cardiac types.
- b. The cardiac's needs in "reëducation for living."
- c. Type of medical supervision essential during sheltered employment and after reëmployment.
- d. Non-medical services needed during the "hardening" and rehabilitation period such as vocational guidance, family social service, and psychological adjustment.

CONFERENCE OF MUNICIPAL PUBLIC HEALTH ENGINEERS

At the October, 1947, meeting of the Conference of Municipal Public Health Engineers in Atlantic City, the following officers were elected for a period of one year:

Chairman—Charles L. Senn, Director, Sanitation Bureau, Los Angeles City Health Department

Vice Chairman—Morton S. Hilbert, Director, Bureau of Engineering and Sanitation, Wayne County (Mich.) Health Department

Secretary-Treasurer—A. H. Herberger, Director, Division of Sanitation, Nassau County (N. Y.) Health Department

All three are Fellows of the Engineering Section of the A.P.H.A.

RESEARCH ON ORTHOPEDIC APPLIANCES

The Mellon Institute of Pittsburgh announces a comprehensive multiple research fellowship to conduct broad scientific investigation and development about orthopedic appliances. Problems of mechanical design, improvements in construction materials, and methods of fitting appliances will receive particular study.

The program is headed by Senior Fellow John R. Young, a research specialist in metallurgy and mechanical engineering. Eugene F. Murphy, Engineer of the Committee on Artificial Limbs of the National Research Council, serves as Advisory Fellow. A medical advisory committee of three orthopedists also serves the fellowship.

The work is made possible through a grant by the Sarah Mellon Scaife Foundation of Pittsburgh.

NAVAL AIR RESERVE TRAINING

The Naval Air Reserve Training Command makes the following announcement:

The Naval Air Reserve Training Command, with headquarters at Naval Air Station, Glenview, Ill., has 17 nationally located Naval Air Stations and 4 Naval Air Reserve Training Units at which Naval Reserve Medical Officers may serve on active duty with full pay and allowances and with the privilege of returning to civilian life at any time upon request. Additional details may be obtained from Chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill.

FIRST TOWNS IN CONNECTICUT TO VOTE FOR DISTRICT HEALTH DEPARTMENTS

The August *Journal* (p. 1079) reported the action of the Connecticut State Legislature in appropriating funds for state aid to consolidated health districts. The October *Bulletin of the Connecticut State Health Department* reports that three towns, Andover, Roxbury, and Vernon, the first with a population of about 9,000, the others with fewer than 1,000, have voted to join district departments of health when neighboring towns take similar action. Four groups of towns comprising 44 of the state's 161 towns have met to discuss the health district plan, but no group has yet officially applied to the State Department of Health to establish a district department of health.

MINNESOTA PUBLIC HEALTH CONFERENCE

The Minnesota Public Health Conference created in January, 1947, held its first annual meeting November 14, 1947, in the Radisson Hotel in Minneapolis. An evening session was devoted to a banquet commemorating the 75th anniversary of the Minnesota State Board of Health and to paying respects

to A. J. Chesley, M.D., who has served the Board for 46 years, for 26 years as Secretary and Executive Officer. The toastmaster was Thomas B. Magath, M.D., President of the State Board of Health.

The newly elected officers for 1948 are:

President—J. Lawrence McLeod, M.D., Grand Rapids

First Vice-Chairman—Melvina Palmer, Minneapolis

Second Vice-Chairman—S. P. Kingston, Rochester

Treasurer—Charles G. Sheppard, M.D., Hutchinson

Secretary—D. A. Dukelow, M.D., Minneapolis

DR. MELENEY HEADS PROFESSORS OF PREVENTIVE MEDICINE

At the recent annual meeting of the Conference of Professors of Preventive Medicine, Henry E. Meleney, M.D., Hermann Biggs Professor of Preventive Medicine at the New York University College of Medicine, was elected President for the 1947-1948 year. A mimeographed directory of persons engaged in teaching preventive medicine and public health in the 88 medical schools in the United States and Canada was issued at the meeting. Copies may be obtained by writing to Dr. Thomas D. Dublin, Secretary, 248 Baltic Street, Brooklyn 2, N. Y.

FIVE YEAR PLAN FOR VISUAL EDUCATION

A community program for developing visual education aids has been developed in New Orleans. The Louisiana State and New Orleans City Departments of Health and the Newcomb Art School of Tulane University have agreed on a five year program of visual aid training and production to cost about \$200,000.

Under the plan the Art School will train undergraduate and graduate students in the production of visual aid materials, produce materials such as still photography; film strips; animated sta-

tistical graphic and pictorial matter; exhibition layouts; pamphlets and posters; provide consultation service; and train selected members of the two agencies in the visual aid program.

The State and City Health Departments will provide a portion of the funds by pooling the money ordinarily used for health educational materials, will provide a visual aid consultant, and develop a joint advisory committee on public health in planning the audio-visual art program.

DUST OR BACTERIA COUNTS

The Office of Technical Services, U. S. Department of Commerce, announces sale of a recently published report which describes a photoelectric counter for use in counting colloidal particles in air to record the presence of dust or bacteria. According to the announcement the counter was designed as a smoke penetrometer for comparisons of concentrations of very dilute aerosols and was used to give rapid quantitative tests of penetrations of gas mask filters. Adaptation of the counter for other uses in colloidal chemistry, biology, and industry are suggested.

The counter is actuated by electric impulses produced by the action on a photoelectric cell of beams of light reflected from particles in a stream of the air being examined as it passes through the counter. The report, "A Photoelectric Counter for Colloidal Particles," can be obtained through the Office of Technical Services, Department of Commerce, Washington 25, D. C. Microfilm copies, \$1.00; photostatic copies, \$2.00.

WORKSHOP ON MENTAL HEALTH ASPECTS OF NURSING

A workshop on the Mental Health Aspects of Nursing is offered by the Catholic University of America June 11-22, 1948. There will be special emphasis on ways and means of incorporating mental health principles in all areas of nursing.

For further information write to: Miss Theresa G. Muller, Coördinator in Psychiatric Nursing, School of Nursing Education, Catholic University of America, Washington 17, D. C.

NEW INFORMATION CENTER ON ALCOHOLISM

The Detroit Committee for Education on Alcoholism, one of 28 such local committees in 14 of the 48 states and the District of Columbia, has opened an information center. The center provides consultation and advice and provides guidance in securing professional treatment when needed, in addition to promoting a continuous educational campaign. One of 15 information centers operated by local committees, this has the collaboration of the National Committee for Education in Alcoholism and of the Yale School of Study of Alcoholism.

BUFFALO CITY-ERIE COUNTY HEALTH DEPARTMENT

New York's largest upstate city with more than half a million population has joined with Erie County in forming a city-county health department. This consolidation went into effect on January 1, 1948, with Berwyn Mattison, M.D., as Health Officer. Dr. Mattison has recently been Health Officer of the City of Yonkers and before that District Health Officer in the Kingston State Health District.

This new health department covers all of Erie County except the cities of Lackawanna and Tonawanda with 1940 populations respectively of 24,000 and 13,000. The respective municipal officials failed to act favorably on the plan to consolidate the services of the entire county. Each city has a part-time health officer.

HERBERT HOOVER SELECTS AIDES FOR FEDERAL STUDIES

It was announced in Washington on

December 18 that former President Herbert Hoover, who heads the U. S. Commission on the Organization of the Executive Branch of the Government, had selected several of those who would make studies in connection with the Commission's work.

The Brookings Institution of Washington has been selected to report upon the health, education and social security functions of the federal government, as well as on the government's transportation activities.

Among the other selections was that of Thomas Jefferson Coolidge of Boston, former Under Secretary of the Treasury, to head a committee to study overlapping administration, taxation, and grants-in-aid between the federal and state governments.

PROPOSED END OF U. S. TAX ON MARGARINE

On December 18, Senator J. William Fulbright of Arkansas introduced into the Senate a bill repealing all federal taxes on oleomargarine on the basis that they are "directly opposed to the spirit of free enterprise."

This proposal is in line with the spirit of a resolution adopted unanimously by the Governing Council at the 75th Annual Meeting of the American Public Health Association (*A.J.P.H.*, Dec., 1947, p. 1623).

According to Senator Fulbright, the taxes and licenses on margarine is the only case where a federal tax is levied on one domestic product for the benefit of a competing product.

MISS FILLMORE SUCCEEDS MISS HOULTON IN N.O.P.H.N.

On January 19, 1948, Ruth Houlton, R.N., retired as General Director of the National Organization for Public Health Nursing, a position she has held since 1942 when she became Director after serving 7 years as Assistant and then Associate Director:

Miss Houlton was succeeded by Anna Fillmore, R.N., who has been with the Visiting Nurse Service of New York since 1940 successively as staff nurse, supervisor, industrial nursing consultant, and assistant director. Previous to 1940 she was Director of the Bureau of Public Health Nursing in the Utah State Health Department and Assistant Director of the American Nurses Association. She holds a B.S. degree from Teachers College, Columbia University, and the degree of Master of Public Health from Harvard University.

Miss Fillmore has held special lectureships at Teachers College, Columbia University, Toronto University, and the School of Public Health, Harvard University, and is the author of several articles on public health nursing and industrial nursing which have appeared in professional magazines.

RESEARCH ON HUMAN REPRODUCTION

Haven Emerson, M.D., Chairman of the National Committee on Maternal Health, which was organized in 1923 by a group of physicians, recently announced the first comprehensive program for research in reproduction to be undertaken. This program will be under the direction of the National Research Council which has established a Committee on Human Reproduction to study needs and, on the basis of findings, to recommend grants for specific research projects. The Planned Parenthood Federation will collaborate in and seek to contribute substantial funds for the research program while its clinics and records can serve as a valuable field for some of the research projects.

The Chairman of the Council's new Committee on Human Reproduction is Howard C. Taylor, Jr., M.D., Professor of Obstetrics and Gynecology at Columbia University's College of Physicians and Surgeons. His committee is made up of 14 experts in several fields; obstetrics and gynecology, urology, anat-

omy, zoölogy, embryology, general medicine, population problems, psychology, psychiatry, and physiological chemistry.

Coincident with this announcement a reorganization of the Board of the National Committee on Maternal Health was completed. Formerly made up of physicians, it is now predominantly a lay board made up of the following persons in addition to Dr. Emerson:

William Harding Jackson, Chairman of the Board of the New York Hospital and Cornell Medical Center, and of the Hospital Council of Greater New York

Frank Notestein, Head of the Office of Population Research at Princeton University

Frederick Osborn, United States representative on the United Nations Atomic Energy Commission

John D. Rockefeller, 3rd.

Dr. Kenneth Rose, Secretary of the Planned Parenthood Federation

Dr. Irvin Stewart, President of the University of West Virginia

Spencer Byard of New York, Legal Council

Sidney D. Gamble of New York, Treasurer

This Board will determine broad comprehensive policies and will appeal to the public for financing the research program.

In commenting on the new program, Dr. Emerson said, "We are confident that the public will support this program enthusiastically once they understand it. Nothing is more obviously important to all Americans than the good health which begins with a sound foundation—healthy mothers and babies."

DR. FLORENCE R. SABIN ASSUMES DENVER POST

Florence R. Sabin, M.D., President of the Western Branch of the American Public Health Association, well known because of her leadership of a public health movement in Colorado and elsewhere, assumed her duties as Director of Health and Charities in Denver on January 1. Dr. Lloyd Florio, Denver, will continue as City Health Officer in the plan for reorganizing the Department.

An effort in Denver to revise the city

charter and to abolish the position of Health and Charities Director was defeated with the November election. Dr. Sabin's appointment is understood to be for the interim until it is hoped the charter can be amended. Dr. Sabin has recently served as Chairman of the Board of Health of Denver and is a member emeritus of the Rockefeller Institute for Medical Research, New York, N. Y.

DR. PARRAN PROPOSES FEDERAL PLAN TO
FINANCE TRAINING OF MEDICAL
STUDENTS

At the conference in Washington, D. C., between the Surgeon General of the U. S. Public Health Service and the Association of State and Territorial Health Officers early in December, Dr. Thomas Parran, Surgeon General, proposed that the United States Government should subsidize medical students as one means of increasing the supply of physicians. The plan was supported at the same meeting in an address by Oscar R. Ewing, Federal Security Administrator.

Also supporting Dr. Parran, the Association of State and Territorial Health Officers approved such a plan and included scholarships in dentistry, nursing, and allied fields. Under this plan those applicants would be admitted to undergraduate medical schools of their choice under a plan similar to that now prevailing for men to attend military and naval schools. The applicants would obligate themselves to spend a month in federal service for each month of scholarship benefit, or at the discretion of the government, in state or local public health service.

Other steps recommended by the Association included federal aid to the states to expand and extend local public health services, federal grants to medical schools, transferral of the activities of the Children's Bureau to the Public Health Service, a more liberal plan for

the loan of U. S. Public Health Service personnel to the states, and the set-up of an inter-agency committee on tuberculosis evaluation methods, including representatives of the A.P.H.A., National Tuberculosis Association, American Medical Association, U. S. Public Health Service, and the Association of State and Territorial Health Offices.

It was also proposed to improve U. S. Public Health Service laboratory services, including the establishment of a national Salmonella typing center, the supply of rare biologicals to public health and other laboratories, and the creation of a national virus and rickettsial identification center. They recommended continuation of the federal appropriations for a national school lunch program and supported steps in the direction of the topical application of sodium fluoride to children's teeth.

CANCER CONTROL GRANTS

The National Cancer Institute made grants of 1½ million dollars to 64 colleges, laboratories, and public health institutions as a result of the recommendations made at the two day meeting of the National Advisory Cancer Council in December. Half a million dollars was made available for research in 32 institutions, more than half a million for the improvement of teaching in medical schools, more than \$100,000 for other projects largely in state health departments, and a quarter of a million for reconstruction of the Roscoe B. Jackson Memorial Laboratory in Bar Harbor, Me., destroyed in the November forest fires. This represents the first substantial construction grants ever made by the Council.

These December grants included other notable firsts. Grants of \$13,000 and \$10,000 respectively to scientists in the Pasteur Institute in Paris and the Hebrew University represent the first grants to scientists working outside the country. "They constitute," said Leon-

ard Scheele, M.D., Director of the National Cancer Institute, "a move to assist in the mobilization of an international attack on cancer." This same meeting produced also the largest grant made to a single institution—\$112,500 to Memorial Hospital in New York for 5 research projects and \$30,000 for cancer pathology and medical training.

BORDER PUBLIC HEALTH ASSOCIATION TO MEET MARCH 20-22

M. F. Haralson, M.D., El Paso, Tex., Secretary of the United States-Mexico Border Public Health Association, has announced that the annual meeting which originally had been announced for late March will be held March 20-22, in Laredo, Tex., and in Neuvo Laredo, Mexico.

The Border Public Health Association is closely linked with the program of the Pan American Sanitary Bureau, Washington. Dr. Haralson, who represents the Bureau in El Paso, would welcome word from public health workers who could be in that vicinity at the time of the meeting.

MANUAL OF RECOMMENDED WATER- SANITATION PRACTICE

This *Manual* presents in concise form the salient features essential to the sanitary control of a water supply system and its operation. It "primarily is to serve as a guide to Public Health Service engineers in evaluating the sanitary features of water supplies with which they are concerned." It should prove equally valuable to state departments of health and others concerned with water sanitation.

Prepared coöperatively by the Water and Sanitation Investigations Station, Cincinnati, and the Sanitary Engineering Division, U. S. Public Health Service, the text is divided into four sections. They cover: Part I, those features of water supply systems which should be included in any survey and which are

important enough so that defects would be detrimental to the safety of the supply. Parts II and III deal with recommended sanitary requirements for water treatment and distribution. Part IV is an explanatory discussion of the bacteriological and chemical requirements for potable drinking water as set forth in the 1946 *Public Health Service Drinking Water Standards*.

May be obtained from the Superintendent of Documents, Washington, D. C., 15 cents.

BALTIMORE MEDICAL SOCIETY REQUESTS MEDICAL CARE PROGRAM EXTENDED

In October, 1947, the Baltimore Medical Society unanimously voted a resolution requesting the Baltimore City Health Department to organize a medical care program such as is now in effect in the 23 counties of Maryland. This program was begun in the state in 1945 in accordance with state legislation authorizing a medical care program through the state and local health departments. After two years of its operation in the counties, the Baltimore Medical Society recommends its extension and promises the Baltimore Health Commissioner "that its officers will be glad to coöperate in every way possible in carrying out this important program."

VAN METER PRIZE AWARD

The American Association for the Study of Goiter again offers the Van Meter Prize Award of \$300 for the best essays submitted concerning original work on problems related to the thyroid gland. Essays may cover either clinical or research investigations, should not exceed 3,000 words, and must be in English, typewritten in double spaced copy. The award will be made at the annual meeting of the Association in Toronto, May 6-8. Address Dr. Thomas C. Davison, Corresponding Secretary, 207 Doctors Building, Atlanta 3, Ga.

PERSONALS

Central States

OTTO A. BESSEY, Ph.D.,* will become Professor and Head of the Department of Biological Chemistry, University of Illinois, College of Medicine, Chicago, as of April 1. He is now Chief, Division of Nutrition and Physiology, Public Health Research Institute, New York City.

HAYSE H. BLACK,† has become Associate Professor of Sanitary Engineering in the Department of Civil Engineering, University of Iowa. He has been the Officer in Charge of the U. S. Section, International Joint Commission Boundary Water Pollution Investigation, Detroit.

JACQUES P. GRAY, M.D.,* has joined the staff of Parke, Davis and Company in Detroit as Medical Consultant to the Sales and Promotion Division. Dr. Gray has a varied public health background in both the California and San Francisco Health Departments and with the Community Health Project of the W. K. Kellogg Foundation, among others.

NEW HEALTH OFFICERS IN ILLINOIS

CHARLES R. KINCAID, M.D.,† has been appointed Health Officer for the Will County Health Department, with offices in Joliet. He was for 3 years each with the Indiana State Board of Health, the City-County Health Department, at Eau Claire, Wis., as Director, and with the U. S. Army.

ERNEST J. BECKNER, M.D.,‡ was recently appointed Health Officer for the Montgomery County Health Department effective October 1. Since 1941 he has served with the Health Department in Pratt County and later with the Butler County Health Department in Kansas.

RACHEL M. LEHMAN, Instructor in

Medical Technology, University of Indiana Medical School, has been elected President of the American Society of Medical Technologists.

FRED LONG, M.D.,* of the Nebraska State Department of Health has been appointed Director of the City-County Health Department, Lincoln. He succeeds CORINNE EDDY, M.D.,† recently resigned. Dr. Long has been directing the preventable disease control work of the State Department of Health and has been acting director of the Division of Venereal Disease Control.

ALLAN STONE,† has been named Executive Director of the Minnesota Cancer Society, a division of the American Cancer Society. For the past six years he has been Research Director of the Amherst H. Wilder Charity of St. Paul, and earlier Assistant Head of the Bureau of Research and Statistics, Minnesota Division of Social Welfare.

EDGAR WILLIAM WARREN, M.D., was recently appointed as Director of the newly established Mental Hygiene Division, Kansas State Board of Health. Dr. Warren has served on the staff of the Louisiana State Health Department, and since January, 1946, with the Menninger Foundation.

Eastern States

P. G. AGNEW, Ph.D., who for the past 28 years has served as Secretary and head of the staff of the American Standards Association, New York, N. Y., retired January 1, but the Board of Directors has retained his services as Consultant.

THEODORE E. BOYD, M.D., has been named associate director of research for the National Foundation for Infantile Paralysis, New York, N. Y. He has been on the faculty of the Loyola University School of Medicine.

PHILIP S. BROUGHTON,* recently joined

the staff of A. W. Mellon Educational and Charitable Trust of Pittsburgh in an administrative capacity. He was formerly public relations counsel of Young and Rubicam, a national advertising agency with headquarters in New York.

CHARLES M. CARPENTER, M.D.,† on January 1, accepted appointment as Professor and Chairman of the Department of Infectious Diseases at the new medical school of the University of California at Los Angeles. Dr. Carpenter was previously Associate Professor of Bacteriology and Public Health at the University of Rochester (N. Y.) School of Medicine and Dentistry.

HOWARD ENNES, Chief, Extension and Training Section, and MARGARET K. LUMPKIN,† Venereal Disease Division, U. S. Public Health Service, have been detailed to New Haven, Conn., respectively as Executive Secretary and Associate in Medical Social Work, with the Cooperative Studies in the Social and Educational Aspects of Venereal Disease Control, a joint undertaking of the Department of Public Health of Yale University and the Venereal Disease Division of U. S. Public Health Service.

ROBERT U. GATES was recently appointed as a representative of the Engineers Joint Council on the U. S. Commission for United Nations Educational, Scientific and Cultural Organization. Mr. Gates is President of the American Society of Mechanical Engineers and a specialist in the design and construction of fuel burning and steam generating installations.

HARRY HEIMANN, M.D.,† has been appointed Industrial Hygiene Consultant to District 1 of the U. S. Public Health Service, New York, N. Y.

With the rank of Senior Surgeon he has been in the Washington office of the Service since 1946. Previously he was in the Syracuse, N. Y., office and in the Division of Industrial Hygiene and Safety Standards of the New York State Department of Labor.

JOSEPH HIRSH,* Associate Director, The Research Council on Problems of Alcohol, New York, has become Director of Public Information, World Health Organization, Interim Commission, of the United Nations. He participated in the Fifth Session of the World Health Organization, Interim Commission in Geneva, Switzerland, January, 1948.

VICE ADMIRAL GEORGE F. HUSSEY, JR., USN (Ret), wartime Chief of the Navy's Bureau of Ordnance, on January 1 assumed his duties as administrative head of the American Standards Association. He will direct the coöperative efforts of industry, consumers, and the government in the vital problem of standardization.

EVA LANDSBERG, M.D.,† has been appointed Chief of the Division for Physically Handicapped Children in the New York City Department of Health, succeeding SAMUEL M. WISHIK, M.D., resigned.

HAROLD H. MITCHELL, M.D.,† recently was appointed Director of School Health for the public schools of Montgomery County, Maryland, with headquarters in Rockville. Dr. Mitchell was previously a district health officer of the New York City Department of Health.

ROBERT W. OSBORN* was recently elected by the board of managers of the State Charities Aid Association of New York as executive secretary of its State Committee on Tuberculosis and Public Health and assistant secretary of the Association. Mr. Osborn is the third executive secretary of the state committee since it was organized in 1907 to fight tuberculosis. He

* Member A.P.H.A.

† Fellow, A.P.H.A.

joined the S.C.A.A. staff as administrative assistant in 1924.

LUCILE PETRY, Chief of the Nursing Division of the U. S. Public Health Service, and AGNES CHAGAS, Nursing Director of the Pan American Sanitary Bureau, are in Mexico City studying the feasibility of establishing a school of nursing at the University of Mexico.

SOL PINCUS, C.E.,* retired as Senior Sanitary Engineer with the New York City Health Department on October 1. Mr. Pincus served with the City Health Department from July, 1935, until his retirement, and at one time held the title of Deputy Commissioner, being in charge of Food and Drug Control and Sanitary Activities for the department. He is now in private practice as a public health engineering consultant.

ARTHUR B. ROBINS, M.D., Dr.P.H.,* was designated as Acting Director of the Bureau of Tuberculosis, Department of Health, New York City, effective September 1, 1947. He has been associated with the department as Supervisor of Clinics in the Bureau of Tuberculosis since 1937.

DEAN THORNDIKE SAVILLE, of the College of Engineering, New York University, has been appointed a member of the New York State Public Health Council by Governor Dewey, filling the vacancy created by the recent death of PROFESSOR HENRY E. OGDEN of Cornell.

Southern States

ROBERT L. CHERRY, M.D.,† in October became Deputy Medical Director of the Eastern Area, American Red Cross, with headquarters in Alexandria, Va. During the war Dr. Cherry served with the Allied Military Government in North Africa and Italy as communicable disease officer for the Public Health Subcommittee of the Allied Commission. He was awarded

the United States Army Typhus Commission medal by the American Government and the Knight Order Crown of Italy by the Italian Government for his services during the Naples typhus epidemic.

Western States

ADDITIONS TO STAFF OF DENVER, COLORADO, HEALTH DEPARTMENT

WARD L. CHADWICK, M.D.,† as Director of Communicable Disease Control. A pediatrician who was a medical officer in charge of venereal disease control in the Army during the War, he was previously pediatric consultant to the Colorado State Division of Public Health.

EVELYN RAHM,* Health Education Consultant with the U. S. Public Health Service, District 8, has been on loan from the U. S. Public Health Service, since September 15.

HAROLD J. BARNUM, as Chief of the Milk Section of the Environmental Sanitation Division. He has been in the public health phase of milk work for 14 years, having served on the National Committee of the International Milk Association continuously since 1933. He is author of several special bulletins issued by the Michigan Agriculture Experimental College, and has been employed in the Milk Division of the City of Detroit, and was in charge of the sanitation program for Ann Arbor.

J. ROBERT CAMERON,† as Chief of the Denver Sanitation Section of the Environmental Sanitation Division, will be in charge of rodent and insect control, and will supervise swimming pools, private water supplies, and act in an advisory capacity for sewage disposal and garbage collection. He was former engineer for the Washtenaw County, Michigan Health Department.

JAMES A. KING,† recently of the U. S.

Public Health Service as Chief of the Education and Training Section of the Environmental Sanitation Division.

RUTH RAATTAMA, M.D.,* as Director of the Maternal and Child Health Division. Recently with the Idaho State Health Department, she has just completed a 3 months' Fellowship at the Mayo Clinic.

HELEN GRIFFIN TIBBITTS, was appointed State Vital Statistics Registrar of Oregon. She has been with the U. S. Public Health Service, and more recently engaged in special studies in the department of sociology, University of Michigan.

Other Areas

MIGUEL BUSTAMANTE, M.D.,† has been appointed Secretary of the Pan American Sanitary Bureau. He was formerly chief of the Epidemiology Laboratory of the Mexico Department of Health.

JESSE C. ELLINGTON, M.D., M.P.H.,* recently received from the Republic of Panama, the Order of Vasco Nunez de Balboa, grade of "Commendador." This is the highest decoration for distinguished public health service given by Panama.

JOHN E. ELMENDORF, M.D.,* Rockefeller Foundation, Bogota, Colombia, was recently decorated as Honorary Officer of the Military Division of the Most Excellent Order of the British Empire, in Bogota. Dr. Elmendorf's decoration was conferred on him in recognition of his work as Director of the U. S. Army School of Malariology in Panama.

HERNAN ROMERO, M.D., M.P.H.,* Director of the School of Public Health, Santiago, Chile, has recently been appointed permanent head of the Department of Hygiene and Pre-

ventive Medicine in the Medical Faculty, where he will be responsible for the undergraduate program.

Death

WELLINGTON PORTER SHAHAN,† Executive Secretary of the Illinois Tuberculosis Association for 18 years, died on November 21, 1947.

Public Health in Britain— The Changing Scene*

SIR ANDREW DAVIDSON, M.D., F.R.C.P., F.R.C.S.,
F.R.S.Ed., D.P.H.

Chief Medical Officer, Department of Health for Scotland, Edinburgh

BACK in the dark days of the recent war the strenuous work of health officers in Britain was much lightened by visits, from time to time, of many distinguished medical colleagues from your country. When the outlook seemed gloomiest, these visits were alike encouraging, sustaining, and helpful. To mention all who contributed in this way would be to repeat a lengthy catalogue of names well known in many branches of American medicine. Without individually mentioning those occurring to my memory I should like to take this opportunity of thanking all who visited us then for the intellectual refreshment which they brought and for the practical advice which they gave during those critical days. For this reason alone my presence here today would be well worth while; but there are others. The opportunity of meeting leaders of public health of this country, of exchanging views, of discussing common problems,

and of observing how these problems are being tackled here, would also of itself be sufficient to make for unhesitating acceptance of your Association's kind invitation to attend this 75th Annual Meeting and to make a modest contribution to its deliberations. Moreover, by inviting me personally, you have honored the Public Health Service of our relatively small—although we like to think important—country of Scotland. My colleagues at home share my high appreciation of this distinction, implicit in your invitation.

But even acceptable invitations bring their problems. In this case the most difficult one to solve is the choice of a subject for my remarks. As public health organization in Britain is in the process of rapid change, it has been suggested that an appropriate theme would be the changing scene in British public health. To me, however, it has at least two limitations. To depict clearly such a scene within the space of a few minutes is well-nigh impossible; and my more intimate knowledge of what is happening is confined mainly to Scotland. The lat-

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

ter, however, is less important for, broadly speaking, the trends are similar over Britain as a whole; and to this extent the task is made easier, perhaps more so, because of the very close coöperation between the Ministry of Health for England and Wales and the Department of Health for Scotland. Nevertheless, any attempt to describe in the limited time at my disposal the changing scene in British public health must necessarily be confined to the broadest outline.

The present year of grace finds us, in Britain, celebrating the centenary of the appointment of the first Medical Officer of Health and, at the same time, standing on the threshold of great new developments in the organization and administration of our National Health Services. We believe that these two events are phases of the same evolutionary process of public health development in our country. A survey of the progress made in the intervening period has helped us to appreciate the philosophical and scientific background of our public health endeavor and to respect the strenuous efforts of the pioneers in preventive medicine. But it does more. It demonstrates the historical reasons for the gaps and deficiencies which exist in our present services and defines lines of approach toward future reorganization. By and large, our health problems have hitherto been tackled tactically rather than in accordance with a strategic plan, for the evolutionary movement began by the compulsion of events associated with the immense industrial developments of the 19th century. In these earlier days effort was mainly directed toward the lessening or, where possible, the removal of harmful environmental influences, the control of epidemic diseases, and the provision of medical attention through the Poor Law system for those unable to pay for it. Behind the advances there was a stimulus of social need although action was

governed by fear rather than philosophy or scientific principles. Moreover, priority of public health problems was determined by the force of public opinion. As the state of medical knowledge advanced, however, public health administration came to rest on a scientific basis.

The change from the approach to better public health through cleansing, drainage, and water purification, to the approach to positive health through social amelioration and preventive and curative medicine, is both a fascinating and an instructive story. It is too lengthy, however, to relate now. As an alternative I shall pick up the thread by attempting to describe where we now stand and to touch on what we hope to achieve in the future.

As I have already indicated, the main and obvious problems which were tackled first have been, in many cases, solved or alleviated. We have traveled far as regards measures designed to prevent certain contingencies such as the outbreaks of old-time plagues. Also we have recognized that conditions not bad enough to create epidemics are nevertheless conducive to inferior physical and mental development, or to the existence of actual disease or impaired health. Thus, housing was recognized as an important influence and the effect of poor housing bore heavily upon those predisposed to mental or physical disease. Likewise, nutrition, especially during the past decade or two, has been made the subject of intensive inquiry and research, with the result that feeding now aligns itself with and, in some respects, takes precedence of housing. But the worker spends much of his day in the factory or workshop; therefore, adverse conditions there have been constantly under review. The wide advances in industrial health bear witness to the resolution with which these problems are being tackled. Similarly, the school environment, in which the growing child spends so much of his time, has been

the subject of a continuous process of improvement for the past 40 years since the School Medical Service was established.

The curative medical services, however, have up till now largely operated independently without being in full and free coöperation with the social and environmental services. Curative medicine has dealt with the casualties but has not always searched for causes any further than in the pathological and bacteriological laboratories. It has been essentially individualistic and therefore has not had the opportunity to verify its findings on a broad statistical basis. Moreover, it has not had the opportunity to search for early departures from the normal where properly applied experience would have laid these probabilities open.

A near approach, however, to a linkage with the preventive services is to be found in our Highlands and Islands Scheme for providing general practitioner, specialist, nursing and ambulance services covering the sparsely populated northern districts of Scotland. These services, apart from bringing the necessary curative medical advice to "the crofters and those of similar economic circumstances," are closely interwoven with the preventive health services, such as School Medical Service, maternity and child welfare, of the local authorities. Again, in the case of the school child, medical inspection, with the detection and treatment of minor ailments, is applied to all school children receiving publicly provided education. The School Medical Service was the first scheme to bring the benefits of preventive medicine to a large group of the population, and to recognize that early diagnosis with early treatment is prevention.

The opportunities are now at hand for all the agencies concerned with health—social and personal, preventive and curative—to get into harness to-

gether. We in Britain are about to project new developments which we hope will go a long way toward that objective. The schemes of the past have been the spearpoint of the attack and they were directed to the most vulnerable, and probably the least regarded, sections of the community. Their operations have brought to light much evidence on which to base future action. They have provided, for example, statistical information on the well-being or otherwise of infants, preschool and school children; they have disclosed the difficulties and dangers of pregnancy and childbirth; while they have given us the yardstick with which to measure trends in health and physical development. But as to the adolescent, the population at working ages, and the aged, information is meager. It is true that a medical service has been provided, through the National Health Insurance Act, 1911, for the working age groups; but this covers only 44 per cent of the population.

In Scotland, for eight or nine years before the war, annual statistics were recorded and published of the incidence of incapacitating sickness of insured persons. These have been helpful pointers to health policy. But in fact, while the National Health Insurance Act provided a sound enough though incomplete scheme for medical care of the individual worker, its influence as an instrument of preventive medicine was less potent. The medical care of the non-insured adult was dependent upon private arrangements or, for those unable to pay privately, through the medium of the Poor Law. It is only fair to say that the Poor Law has for many years provided a reasonably satisfactory individual and hospital service for those who came under its care. Its service was restricted, however, by financial qualifications and it varied in efficiency according to the type of local authority. The Poor Law

as a means of succor for the sick, and indeed for the able-bodied, is now likely to pass into the limbo of forgotten things and to be replaced on the one hand by a National Health Service which will be available to everyone, and, on the other hand, by a system of national assistance for those who require material help.

A new outlook on long-term or chronic incapacity, sharpened by the influence of war, finds expression in the development of rehabilitation as an instrument of prevention. For many years—indeed, since World War I—orthopedists have given attention to the benefits it provides for the surgical cripple. Now more interest is being shown in its possibilities in general surgery and in general medicine. No longer can the medical or surgical worker remain satisfied if he has merely succeeded in postponing the event of death or guiding his patient through an acute illness into quiescence or chronicity. He must aim at rehabilitation. The patient must be returned to circulation as an active healthy worker or brought to as high a grade of fitness as possible.

The idea of rehabilitation is accepted, but to achieve its complete fulfillment involves coöperation with other government departments than the Health Department, and with industry itself. If a patient through a residual disability is prevented from returning to his normal occupation, steps must then be taken to fit him into another occupation so that he shall not fall into the scrap heap of the permanently useless and unfit. Therefore there is now on the Statute Book the Disabled Persons Act, 1944. This Act provides for the registration of all persons with a disability and it compels employers to employ a proportion of disabled persons. It enables the Ministry of Labour to give such training as may be necessary to fit a disabled person for a new job, and to provide sheltered occupation for those for whom industry can offer no opening. Reha-

bilitation applies to both medical and surgical cases. It is an essential part of preventive medicine in the future because it has become clear that the provision of a useful and satisfying occupation is one of the strongest psychological factors in maintaining and in regaining health.

The changing age constitution of the population, with the increased weighting of the older age groups, is directing more and more attention toward the care of the old people and of the chronic sick. It has been in this field of health effort that the old Poor Law system has made an important contribution. Within recent years a more enlightened view of the care of old people and the chronic sick has been evolving; and, at the present time, there is a stirring of the public health conscience concerning the previous neglect of those problems. All this is reflected in the increased interest by many organizations and the establishment of important research groups for the medical and social study of the aging population.

The mental services in the past shared with others the handicap of dealing only with well established diseases. Psychological medicine received a great impetus during the recent war, and the experience gained in both the grading and the assessment of mental aptitude and in treatment will, it is hoped, be translated into practice in civilian life. The influence of mental conditions on the causation or aggravation of bodily illness is now being scientifically investigated. The adverse effect of misfitting the man to the job is realized; and no doubt the newer methods of analysis will in time be used more and more in selection for employment. The boundaries between neurosis and disease of known structural pathological change are being explored and may lead to a clearer comprehension of many of the causes of disability and breakdown.

An almost intractable problem which

courses through our preventive and curative services, more intensive in the fields of tuberculosis, mental health, and chronic sick, is that of providing nurses. Recently a special group of investigators has inquired into this complex matter on behalf of the government, and their report* is awaited with intense interest by all concerned in the operation of the health services.

As regards the social provision against breakdown and accident, there have been enacted within the past year the National Insurance Act and the National Insurance (Industrial Injuries) Act. These two provide for insurance against sickness, unemployment, and injury.

Housing, of course, maintains its eminence as a public health problem, but economic factors are inhibiting progress. One recent development, however, is the advent of the New Towns Act which aims at the development of new areas rather than the extension of existing population overgrowths. In such an industrial country as ours—for example, in Scotland, four-fifths of the population live on one-quarter of the country's area—a spreading out of inhabitants is a prime public health measure.

The feeding of the nation during the war was, of course, the province of the Ministry of Food, and the activities of that ministry have succeeded in maintaining an equitable distribution of food among all classes. The distribution has been carried out with due attention to the qualities of the nutrients required and to the quantities needed by various sections of the community. Thus, the interests of the young and the factory worker, have been safeguarded. The expectant and nursing mother has had secured to her the food that she needs. This is an important social experiment and has brought nutrition into a prominent place in administration. Its reper-

cussions on health are apparent and no health policy in the future will neglect this most important subject.

Education has an important part to play. The young must be taught the rudiments of healthy living, and the schools have an important function in the health services in this respect. It is to them that we must look for the development of the correct attitude to health in the citizens of the future. The education authorities as well as the health departments have had laid upon them the duty of safeguarding the health and insuring the treatment of school children; so there is a double check on the welfare of this important population group.

Thus in the health field we have to consider the influence of several ministries, each of which has something important to contribute. The success or otherwise of their policies must be taken into full consideration in formulating future developments.

Apart from the environmental health services, we have at the moment organized personal services for the care of the young, the expectant mother, for certain diseases such as tuberculosis, infectious diseases, and a less organized service for cancer. Moreover, there is a partially organized service for health in industry and for curative medicine in hospital, and at home as regards the adult-working population. The aged and the chronic sick have been cared for to some extent and the other non-medical services which I have just mentioned, namely, social insurance and nutrition, have been developed.

But few, in Britain, will deny that our national health services have been developed in a piecemeal fashion. The new objective is to bring them together within a comprehensive health policy which takes into full consideration the changing medical outlook toward health and the prevention of disease and disability; the developing conception of

* Published September 11, 1947.

social medicine; the importance of psychological factors in disease; the close relationship between health and industrial efficiency; and the key position of health in any complete scheme of social security.

To achieve this objective an essential step is to train the personnel of the health services in accordance with the lines of that policy. Already a start has been made with medical students, undergraduate and postgraduate. The General Medical Council, the body charged with the responsibility for maintaining a satisfactory standard of medical education, has recently adjusted its educational program giving more attention to preventive medicine and to the social and psychological aspects of sickness and disability.

Now we are facing other developments designed to improve the existing services, to fill in the gaps and to keep a running audit of progress. The new National Health Service Acts—one for England and Wales and a separate one for Scotland—place on the Minister of Health for England and Wales and on the Secretary of State for Scotland the duty of providing a hospital and specialist service for all members of the community, also a general practitioner

or family doctor service including dentistry, home nursing, and other adjuncts. The duty still remains with local authorities to provide the services of preventive medicine and health education as well as the original environmental health services. The hospital and specialist services are to be operated through a different organization from the family doctor service. Thus, there are three separate administrative units to be built up and the problem will be to keep them in harmony with one another. The problem of their integration is, of course, a real one, but since the danger of separation is recognized the necessary administrative measures for securing unified action and coöperation are being taken. We believe that the proposals in these Acts represent a bold and purposeful step forward. As health administration can never be static and as experience of the new arrangements emerges, further advances may be anticipated in the course of time.

These remarks contain a brief and necessarily incomplete survey of the changing scene in British public health, yet they may serve to show how we are wrestling with the current problems and how we are endeavoring to face the future.

The Health Officer in Post-war Britain*

SIR ALLEN DALEY, M.D., F.R.C.P., D.P.H., K.H.P.

*Medical Officer of Health, County of London, England, and
President, Society of Medical Officers of Health*

WHILE we are celebrating here the 75th anniversary of your Association, I bring to you the greetings and cordial good wishes of the Society of Medical Officers of Health of Great Britain—an institution now 90 years old.

I believe that this country appointed health officers long before we did in Great Britain. In fact, it was only in 1847 that the first medical officer of health was appointed in England—Dr. Duncan, of Liverpool—and the second, appointed by the City of London in 1848, was the famous Dr. (afterward Sir John) Simon, whose writings will be well known to most of you.

I will not weary you with an account of the progressive development of the British Public Health Service. Suffice it to say that it was born to cope with cholera, smallpox, and typhus fevers, and with gross insanitary conditions. During the past forty years its activities have extended more and more into the field of the personal health services, and hospital care and management have been major responsibilities during recent years.

The Coalition Government produced a plan for integrating voluntary and municipal hospitals on the basis of a local government service. The volun-

tary hospitals would have retained their status but would have been subject to an overall plan as to uses and would have been heavily subsidized by public money. The new government brought out early in 1946 a revised scheme which has now been approved by Parliament and within a few months will be implemented. The basis of the scheme, as was that of the Coalition, is a comprehensive medical service free to all at the time of need, though the universal National Insurance Scheme with which it is linked requires weekly contributions from every family. The transfer from Insurance Funds will, however, meet only about a quarter of the total cost of the Health Scheme. There are three pillars of the scheme, but the medical officer of health has direct concern with only one of them.

The first pillar is the hospital and specialist service. At present the local authorities provide a hospital service but there are in most areas a number of voluntary hospitals as well. In London, the municipality provides over 70,000 hospital beds and the number of beds in voluntary hospitals occupied by Londoners is under 20,000. In the new scheme, all hospitals except those run for private profit, are to be taken over by the Central Government. This has certain advantages. Competition and rivalry between municipal and voluntary hospitals will disappear and there will no longer be vexatious limitations on the admission of patients which in a

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

scheme based on local government must depend on where they happen to live.

It is also recognized that a comprehensive hospital service must be based on a large area. It is generally agreed that a population of some two million inhabitants at least is needed and, except for London and possibly Middlesex, no individual local authority area contains a sufficient population. The government has realized the risk of over-centralized bureaucratic control and has devised a system of decentralization which, so far, is unique in the administration of a public service. The country is divided for hospital purposes into fourteen regions. Each will be in charge of a regional hospital board nominated by the Minister from names suggested by the universities, the teaching hospitals, the doctors, the local authorities, and those now administering voluntary hospitals. They, in turn, will devolve the day-to-day management to local hospital management committees each responsible for about 1,000 beds in one hospital or in a group of hospitals.

Financial control must dominate the situation, and success or failure, contentment or discontentment of the staffs will depend largely on its looseness or tightness and how control is effected. The velvet glove is essential in a service such as this. All specialists will have a hospital attachment, and the regional hospital boards will be responsible for the specialist service which is, under the scheme, to be available for domiciliary consultations.

The taking of hospitals out of local government means that medical officers of health will lose their control of fever hospitals, which they have held since they were first built seventy to eighty years ago, and also of tuberculosis sanatoria, which they have had for over thirty years. It has also reversed the policy of the past twenty years, which has been directed toward building up all the local medical services under the

same administration, that is, the major local authority and its medical officer of health.

Another of the three pillars of the new service—the general practitioner service—never has been in the local public health departments except for the domiciliary treatment of the destitute sick under the Poor Law Acts. The new provision of a general practitioner service available for all is a natural development of medical benefit under the National Health Insurance system which started in 1913. The local administration of that service has been the responsibility of the local insurance committees. There is one for each major local authority and the local authority itself has a small representation upon it. The organized medical profession has always fought against domination or any form of control by local authorities and hence their insistence in 1912 that the local insurance committees, though covering the same areas, should be completely independent of the local health authority and, incidentally, of its medical officer of health. The medical profession has representatives on these insurance committees which receive advice, therefore, on medical matters from them. The new councils to be responsible for the general practitioner (and the dental) services are to cover, as did the insurance committees under the National Health Insurance Act, the same areas as those of the major health authorities, but the representation of the health authorities is to be strengthened, being one-third of the total. Unless, however, he is nominated to membership by his authority, the medical officer of health has no part in the work of these "executive councils." There is strong representation of the medical profession on these councils.

We now come to the third pillar. This is composed of the major health authorities, the counties and county boroughs renamed the local health authorities. The

local health authorities have many important duties in the new regime. Some are old duties, some new, and some which were formerly powers are now turned into duties.

At this stage I may point out that the new National Health Service Act makes no mention of the environmental health services—legislation concerning them remains unchanged. The duties of local health authorities are to provide a child welfare service (the Education Act of 1944 had placed on the major local authorities the duty of providing a school health service), a domiciliary midwifery service, a health visiting service, a home nursing service, an after-care service, and an ambulance service. Provision must also be made for immunization and vaccination. There is also power to provide a home help service. All the above, in some form or other, is a development of existing services. It is interesting to note that the methods to secure voluntary immunization against diphtheria have been so successful, and the laws for compulsory vaccination had been so weakened by the conscientious objection clause under which some 50 per cent sought and gained exemption, that the almost century-old Vaccination Acts have been repealed.

There is, however, one entirely new duty placed on the local health authority which may well be the seed from which a mighty tree will grow. This is the provision of health centers from which general practitioners will work in group practice. These centers are to be provided by the local health authorities, who will be responsible for the provision and maintenance of the fabric and for the non-medical personnel, including nurses and clerks. The doctors and dentists who work in these centers will, however, be employed and paid, not by the local health authorities, but by the executive councils. The conditions of service will be settled nationally by negotiation between the Ministry of Health

and the professions. The extent to which doctors and dentists will be willing to work in health centers rather than in their private surgeries is by no means clear, and a serious administrative problem arises as to exactly where new health centers, which obviously must be on an experimental basis, should be located. New housing estates, to which new doctors will have to be imported, are an obvious first choice, but otherwise there is a considerable element of doubt whether the existing local doctors who join the new service will wish to use them. Health centers cannot be built, or even adapted from existing buildings, in a trice, and it will need much administrative skill to insure that the doctors who wish to work in a health center have one available when and where they need it, and, *per contra*, if a health center is provided first, that the local doctors and dentists will use it. I should add that these health centers will, we hope, be associated closely with the various other activities of public health departments and contain within the curtilage or in adjoining buildings maternity and child welfare and school clinics of various sorts.

To sum up the past, the trend was definitely to make the medical officer of health the chief administrator of all the health and hospital services in his area. He was becoming less and less concerned with the environmental services—all that was reasonably necessary had been done or the work was passing to expert technical hands, e.g., housing clearance areas are being dealt with on the reports of surveyors on town planning grounds rather than on the reports of medical officers of health on health grounds, the collection and disposal of household refuse is rightly being transferred from health departments to the engineer or often to a separate department of its own. The medical officer of health is still, of course, the watch-dog over the purity of the water supply and

on prevention of river pollution, but he has no technical responsibility for the engineering side. Sanitary inspectors are more highly educated than they were and are pressing to have independent commands. While these environmental services were occupying less and less of the time of the medical officer, the personal health and the hospital services needed more and more of his attention.

Another trend must be noted and that is recognition of the fact that responsibility for the administration of public health services must be in the hands of authorities sufficiently large to assure the financial resources necessary to do the work properly. Further, the child health and the school health authorities should be the same. This is leading to a transfer of certain services from the smaller to the larger authorities. Demonstrations of local civic pride and much heart burning have been noted in some of the areas from which functions are being transferred.

To revert to the health officers of the large authorities, the medical officer of health of a county borough or a county council will not only have responsibility for the important services entrusted to the local health authorities, some of which have been already listed, but, as the Minister of Health has recently said, he will be the bridge which joins the other two parts of the service—hospitals and family doctor service—to the health service. Opinions differ widely as to whether or not it is a good thing to put the hospital and health services under separate administration and so reverse the trend of recent years. The main justifications for the separation have already been touched upon. Others are that the increasing cost of hospitals would cast a heavy burden on local finance, and the reluctance of voluntary hospitals and the specialists who work in them to be subject to local government control. The arguments against that

are that the health service depends on hospitals for much of its work, e.g., fever hospital beds, maternity beds, beds for cardiac rheumatism, and for the tuberculous. If the health officer could rely on getting his needs for hospital beds met on demand the question of which authority administered a hospital would not much matter, but as people who are hospital administrators now, we know that all demands cannot be met and the priorities given by a purely hospital administration if it has the last word may not be the same as would be given by a health officer controlling a hospital service. The answer to this may well be that the Ministry of Health and not the regional hospital boards will have the last word as to the disposal of beds, but intervention at this level would not be conducive to a happy relationship between the hospitals and the local health services.

Liaison committees of officers to try to solve the interlocking problems will, of course, be necessary, but the hard core of the matter is that the health officer will not be able, as he can now do, while he controls a hospital service, to *direct* that particular classes of patient must have priority in admission because it is of importance to the public health. A further point I may mention, which, no doubt, affects you too, is the increasing amount of time we have to spend in conferences and committees to the detriment of our executive and field work. As a result we have insufficient time for thought and calm reflection on matters of really high policy or on new projects for improving the public health.

The health officer of the future must have access to the basic facts of morbidity for his area if he is to do his job effectively. He now has information about mortality and about the notifiable infectious diseases, but he needs to know much more than that. He must have detailed information about the incidence of *all* the diseases which occur in his

area, and a vast field of research and of subsequent action would be opened if he had access to the records of the hospitals and of the general practitioners of his area. The new service for the first time gives an opportunity for this. But the health officer must have not just the gross figures for a large area. He must be in a position to have access to the *detailed* facts so that he can analyze them in such a way as is likely to lead to conclusions from which action can be taken. For example, it will not be of great value for him to know that rheumatic diseases, neuroses, chest or gastric complaints are unduly prevalent in his area as a whole. He must be able to find out whether the incidence is general or localized to particular districts, to particular types of housing, or to workers in particular factories.

I mention this, despite what I said earlier about the severance of the hospital from the public health side, because we will now have all hospitals in the same service and a general practitioner service which all, men, women, and children, are entitled to use and which the vast majority will use. I trust that by good will on the part of all, such coöperation as I have indicated will enable this important information to be available. I envisage that in the future the public health officer will be regarded as a friend and colleague by those working on the curative side. I remember the days when general practitioners were critical of the public health departments' clinic services. Those criticisms are now heard seldom, but one hopes they will disappear entirely when, for the great mass of people, payment will be on a capitation or salary basis and not on a fee per consultation or attendance. The general practitioner health centers should bring the general practitioners and the health officers working there into a close and amicable relationship such as has never existed before.

One more point I may mention, and that is the development of the social welfare side of public health work. This is becoming increasingly important and covers a wide range: rehabilitation after accidents and serious illness, the fitting of the tuberculous, the crippled, the blind, and the deaf into the community in such a way that they are not a burden to themselves or to the community or, at the worst, that they are the least possible burden, etc. Medical advice and guidance for the planning and administration of this type of scheme are essential, but a question arises as to whether the whole administration need be under medical control. Our Poor Law system, dating from Elizabethan times, is being broken up. The payment of cash benefits will go to the State but much welfare work will remain with the local authorities. Should it be in the public health departments or should a separate social welfare department, parallel to the public health department, be established? and if the latter, what should the line of demarcation be? The views of public health officers and of those now engaged in the Poor Law and social welfare departments may well differ on this matter.

I have indicated some of the problems about which we are thinking on the eve of a radical change in the British public health system. It is clear that new and enlarged spheres of work are unfolding and we must be prepared to grasp and develop them. One general principle which emerges from my presentation of the new scheme is to emphasize that under it the treatment of disease either by specialists or by general practitioners is to be outside the purview and responsibility of the health officer. It is argued by many that this is sound and that better preventive work will be done if the health officer concentrates all his energies on prevention. This may be so, but prevention of serious disease often means looking for the early case and get-

ting it treated in hospital or otherwise. The new conception of social medicine means instilling the idea of prevention of future breakdowns in health into the hospital staffs and general practitioners, and making them conscious of the importance of domestic, economic, industrial, and environmental factors. Are they more or less likely to absorb these ideas if the preventive side is under a separate authority? Time alone will show. It is perfectly certain, however, that with the relatively high cash benefits to be given under the new insurance scheme and with the ever rising costs of hospital treatment every effort will have to be made to prevent ill-health, and there is no doubt that the importance of the health officer will be increasingly recognized.

The scheme is a courageous attempt to provide a really comprehensive health and treatment service freely available to all. No doubt modifications and changes

will be needed as the result of experience. Medical officers of health have been critical of the scheme and some only of their criticisms have been met, but I can assure you that they will play their part ungrudgingly in what is both a conception on the grand scale and a great experiment. They believe that they have sufficient power and influence to insure that the preventive idea will eventually permeate the whole of the medical services of the country and that the triumphs of the past will be repeated in the future.

I have set out these various points because in every country there is a movement to provide, at varying speeds, a better public medical service, and the problems which in Britain confront us today may equally be yours in a few years' time. By then, we in Britain can tell you how our scheme has worked, what are its weaknesses and what is its strength.

Training of Sanitary Inspectors

The New York State-Rensselaer County Public Health Training Center at Troy is conducting a 12 week course for sanitary inspectors in coöperation with the U. S. Public Health Service. The course is designed as practical instruction for apprentice sanitary inspectors and as a refresher for qualified personnel. There are no tuition fees and the local health departments whose workers are being trained are expected to furnish transportation and maintenance for their workers in addition to

regular salaries. The course is limited to 12 workers from New York State local health departments.

Additional courses of about 15 persons are planned for May and September. For these courses about one-third of the students will be accepted from other states. For application forms and details apply to New York State-Rensselaer County Public Health Training Center, Rensselaer County Health Department, 7th Avenue and State St., Troy, N. Y.

The Coördination and Integration of the Public Health Program*

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A.

Dcan, School of Public Hcalth, University of Michigan, Ann Arbor, Mich.

THE success of a public health program is largely dependent upon good team work engendered by all who participate in the promotion of personal health and the integration of the individual's well-being into the collective entity which we call public health. Many are the facets in the training and experience of the members of this public health team. We are not limited to representation from the official health agency but we serve the voluntary associations, the cultural and educational organizations, the physicians, dentists, and veterinarians in private practice, and, indeed, we represent large segments of the very public which we aim to serve. In spite of this diversification in our professional background which one finds reflected in opinions, attitudes, and patterns of approach to health matters, there is a common thread which binds together our interests in the field of public health. This bond which unites the members of the health department staff and impinges smartly on the responsibilities and functions of the medical health officer, the public health nurse, the health education specialist, the public health engineer, and veterinarian, is health education. Through health education, personal health becomes integrated into public health and the latent interest of the individual becomes the

effective participation of the masses.

Health is a living entity influencing the behavior and habits of those who must participate in its attainments if we are to enjoy maximum freedom from disease and accident. Society demands security against the unnecessary illnesses and accidents which impose physical and mental impediments upon people at every age and of every social and economic level, depriving them of the normal, useful, and gainful lives to which a free and democratic nation is entitled. Health is definitely a purchasable commodity, as essential to man's well-being as food, fuel, shelter and clothing. But health education is only a catalyzer which provokes and encourages personal and public participation.

Fundamentally, we must begin with a philosophy for our public health program and include in its structure those elements which make it a complete entity. Before we can coördinate and integrate the program, we must have sound basic data and factual information to serve as a foundation. Identification of such data for community health planning is provided by (1) morbidity and accident statistics, (2) mortality statistics, (3) birth, marriage, and population records, (4) special surveys, and (5) the official records of the health departments, visiting nurse associations, voluntary health agencies, the schools and other organizations. Accuracy in such statistical data provides a reliable and nutritious medium upon which to implant the careful analyses of our bio-

* Presented at a Joint Session of the Public Health Veterinarians and the Health Officers, Public Health Nursing, and Public Health Education Sections, of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

statisticians from which we harvest plans which direct our programs in public health administration and health education. To operate such plans successfully and efficiently, we require health facilities which are available and within the financial reach of all people. Thus, we complete the fabric of our health program by including (1) basic data, (2) facilities, and (3) economic considerations, and by binding these together with (4) health education.

Let us examine for a moment some of the needed facilities. In order to provide full expression for the sanitary and medical programs and thus profit by the art of public health practice, there is needed for each local area within the United States a city, county, or district health department, organized on a whole-time basis and providing as a minimum the six basic health functions emphasized by Emerson¹—(1) vital statistics, (2) control of communicable disease, (3) environmental sanitation, (4) public health laboratory service, (5) infant and child health services, and (6) health education for the general public. Support for such a local health department will continue only if the health director develops a sound public appreciation of what the department is doing for its constituents. This confidence must be built around the department, upon all of the employees and their services, and not focused on the personal ambitions of the director or any other single member of the staff. When inquiry was made of a distinguished state health commissioner as to what he ascribed his long tenure of office, he replied promptly that it was due to his policy of developing a public appreciation of the work of his staff and coworkers that he had become recognized as the head of a state department which was giving adequate professional service to the people of his commonwealth.

Because of its professional character,

the health department like the department of education becomes one of the most expensive services of local government. The health director and the members of his staff should be among the best paid public officials. Unlike the usual run of political office seekers, these are highly trained and skilled professional men and women who have devoted years to specialized training and who undertake their responsibilities on a career basis. The health department needs should be expressed in the basic budget provided through the tax resources of the city, county, or district. To this basic budget there may be entered as a credit allotment from state and federal sources. However, a securely established local budget as a nucleus for the maintenance of the health department with promise of continued public support becomes the *sine qua non* of a good department. Return must be made on money that the public invests in the health service, returns in service, illness and accidents prevented, deaths postponed, health knowledge and understanding extended. Failure on the part of the health director to report appreciable service and results invariably means a shrinkage in appropriation and ultimately the disappearance of the health department itself. Team work in the dissemination of health knowledge by all professional members of the health department staff is the key to good service and adequacy in the health program. The physician, dentist, engineer, nurse, and health education specialist must work together on a coordinated program omitting no opportunity to stimulate public understanding and participation.

The Emerson report¹ recommends that "for a community of 50,000 persons there will be needed one full-time professionally trained and experienced medical officer of health, a full-time public health or sanitary engineer, and a sanitarian of non-professional grade,

ten public health nurses, one of whom would be of supervisory grade, and three persons for clerical work." It is further expected that part-time medical and dental assistance will be sought and that the state health department will provide certain consultant and advisory services in health education and other fields. For populations of larger size, proportionate increases in personnel will be required, with provision for other specialists in the medical, laboratory, dental, nutrition, and health education fields. These suggestions are intended to serve only as a guide for the average community and represent the bare minimum for acceptable practice.

In providing the staff for a local health department, one must give consideration to both quantity and quality of personnel. The various *Appraisal Forms* developed by the Committee on Administrative Practice of the American Public Health Association have emphasized quantity although quality has not been altogether overlooked. In the newer *Evaluation Schedule* an attempt has been made to emphasize both. They seem interdependent. The quantity of service is dependent upon (1) the extent and character of the problem, (2) the unit of time for the service, and (3) the frequency of service. Generally, only a complete local survey of the community can provide the answer regarding the extent of the problem. In this connection the *Evaluation Schedule* has been most helpful, and provides a standard for comparisons between communities and within the same area in point of time. The quality of service can be safeguarded by the establishment of standards for education and experience by the employing agencies. Standards suggested by the Committee on Professional Education of the American Public Health Association are increasingly used by civil service and other merit systems, and may well be made a condition of grants to local health units by

state health departments and the federal government.

In the health department there is no conflict between the interests of the health education specialist and the public health nurse. The former deals in broad community relationships and serves as staff adviser to the latter. The specialist, who should be basically trained in the biological sciences and education is (1) a member of a team working with the staff, (2) planning health education programs for all divisions of the department, (3) sharing skills and techniques, (4) assisting in staff education, (5) employing in her community program such tools as meetings, groups, radio, visual aids, newspapers, bulletins, etc., (6) integrating health education into programs of community agencies, (7) cooperating with physicians, dentists, veterinarians, and other professional groups, (8) cooperating with the schools, and (9) helping people in the community assume their responsibility in health matters. The principal tools are (a) the printed word, (b) the spoken word, and (c) visual education. The public health nurse carries the educational program more intimately into the household and by performance, aid, and demonstration activates the participation of those whose behavior it is intended to influence. And why limit this educational function to these two groups? It is the function of the health director himself, the specialist in environmental health, the clerk in the office, the telephone operator, and information clerk. And why limit ourselves to the health department personnel? Widen our facilities to include the representatives of the voluntary agencies, the physicians and dentists in private practice, the school teachers and, in fact, all groups which admit an interest in the furtherance of personal health and the conservation of public health.

Illnesses and accidents, hindrances to positive and wholesome health, con-

stitute a people's plague, and coöperation and participation of all is essential to the fulfillment of our health program. Coördination and integration must become embedded in the philosophy and actions of the public health team extending from the commissioner's office to every office and service in the de-

partment and reaching out to coöpt the latent resources of other groups, agencies, and individuals which can be harnessed to the goal of better health.

Training Resolution of the Association of State and Territorial Health Officers

The following resolution was adopted by the Association of State and Territorial Health Officers at its annual meeting in Washington in December:

WHEREAS, the Committee on Professional Education of the American Public Health Association, after considerable study, has set standards for certain technical and professional public health personnel, and whereas this committee plans to set standards for as many categories of public health positions as is practical, and

WHEREAS, schools of public health and other organizations are presently training a number of technical and professional public health personnel, and

WHEREAS, there is need for raising personnel standards in various health departments of the nation, be it

RESOLVED that the Association of State and Territorial Health Officers recognize the desirability of adherence to the standards for technical and professional public health personnel recommended by the Committee on Professional Education of the American Public Health Association by organizations employing public health personnel and the desirability that schools of public health and other organizations offering training in the field of public health aim their training programs towards these standards.

Graduate Training of Engineers in Public Health *

JOHN M. HENDERSON, C.E., F.A.P.H.A.

*Professor of Sanitary Science, Columbia University School of Public Health,
New York, N. Y.*

DURING the first third of this century, several diseases of insanitation were so prevalent in this country that the activities of health departments in environmental sanitation were confined largely to their control. Measured by sheer incidence, these may be considered as: the environmental enteric infections, malaria, and hookworm disease. The scope of control activities was narrowed still further by other forces. The enteric diseases were national in extent and thus received more attention than the regional problems even though at times these—malaria, hookworm, etc.—might have been greater. The attack against the enteric infections was further concentrated against those modes of transmission which were most amenable to control. The epidemic situation attracted more attention than the endemic, although the latter often was greater. The sanitation of cities took precedence over that of rural areas. The resultant effect was to give greatest prominence to the fields of municipal water and sewage, including their treatment aspects.

Another characteristic of past practice was the concentration of public health engineering services in state, rather than local, health departments. This still further encouraged the narrowing of

interest in sanitary matters and clinched the case for the water supply and sewerage fields. The scope of state services was confined largely not only to urban problems, but more particularly to those municipal utilities for which local managerial services were available. Moreover, the pattern of state office service encouraged specialization by the individual within these limited fields.

The character and scope of graduate training available to public health engineers during that period largely reflected these conditions. Since there was little distinction at first between the work of the engineer in the embryonic bureau of sanitation of the state health department and that of his colleague in private practice, training for public health engineering was accomplished by admitting the student to existing courses which had been designed for those preparing for private practice or research.

The nation-wide incidence of the environmental diseases cited has now fallen to a comparatively negligible level, due to the influence of sanitary and other public health activities, and economic, biologic, and sociologic change in various complex combinations. This near-disappearance of old enemies has been accompanied by the acquisition of new knowledge in the control of what were viewed formerly as lesser disease problems, by rising standards of living, and by increased public demand for governmental services in public health, including those leading toward the better-

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

ment of health and freedom from obnoxious nuisances. These and other factors have given impetus to expansion in local health service, both in geographic extent and in adequacy of service rendered.

The resultant effect on public health engineering has been twofold. First, present indications are that the majority of future openings for public health engineers will be in local health services—with cities, counties, and small districts. Second, the scope of public health engineering is broadening. The engineer in local health service is faced with problems in many fields, all possessing a nearly-equal level of significance. Many of these men also must possess ability in executive direction, planning, and administration.

In terms of graduate training, the need for more comprehensive instruction has been recognized in some quarters. One manifestation has been an expanded interest in field training for engineers as a supplement to graduate academic instruction. Recent steps by the U. S. Public Health Service toward the development of a number of regional field training centers are commendable. It is hoped that full advantage will be taken of these and other competently managed field facilities by engineers upon completion of their graduate academic studies.

In graduate academic training, the pattern of courses described in the recent report of the Committee on Professional Education (*A.J.P.H.*)¹ represents in outline the curriculum offered by those schools which recognize the need for comprehensive programs of study. In some, the indicated coverage of principles of public health, principles of sanitary science, and of applied engineering sciences, has been resolved into a curriculum which devotes half of one academic year to required subjects in sanitary science and public health, and the remaining half to a wide choice

of advanced electives in sanitary fields.

In the design of such a curriculum, the opinions of supervising public health engineers attain special significance. These individuals, from experience acquired, should be qualified to indicate many of the graduate educational needs of subordinate personnel, and to evaluate the quality of such training by observation of the finished product. The opinions of members of this group may well be the most significant single consideration among the many which enter into curriculum design. This applies most particularly to optional programs of advanced study in the second half of the year.

In the fall of 1946, a request for opinion as to the importance of specified subjects was mailed by the author to the state health department directors of engineering bureaus or divisions of sanitation, and to the engineer-directors of 14 principal city or city-county health departments. The limited number of directors with local health departments who were circularized was due to decision to restrict the poll to those engineers who were known to be supervising other engineers and thus were in a position to make a more objective, and perhaps more complete, appraisal than personal experience alone might permit.

Replies were received from 23 state health departments and 8 local health departments. Submissions from many states represented the joint opinions of several senior members of the bureau or division. A majority had narrative comments appended; these were as significant as the completed forms. As will be seen from Chart I, a representative geographic distribution was obtained.

In order to collect more revealing data, many fields of sanitation and other subjects were subdivided into components; thus Milk Sanitation consisted of 8 line items, but it was explained that these would not constitute separate

subjects in the curriculum. In general, subjects of oldest standing in academic curricula were not subdivided to the same degree as were newer ones, since the former were more simply classifiable into commonly recognized elements. This procedure resulted in 89 line items, grouped into 16 sections. A sample of the form is shown in Chart II.

Aside from the minimum requirement of a B.S. degree in engineering, no other eligibility standards were set forth for the student for whom the course was to be designed. Additional specifications were deliberately omitted in view of the diversity of educational qualifications and experience possessed by students accepted for graduate training by different schools. The primary categories include the baccalaureate degree holder in engineering without public health experience, those with at least 3 years of experience as well, and those who also possess a previous graduate degree, with or without experience.

The replies received were summarized by several statistical procedures, and the remainder of this article is devoted to the presentation and discussion of results obtained under the main column heading *Importance in Curriculum* (see Chart II).

The popularity of line items was first measured by recording only votes posted in the sub-column *Essential*. Votes under the 4 sub-headings *Essential*, *Important*, *Desirable* and *Unimportant* were then weighted in the order 5, 3, 1, and 0, and the results for each line item were consolidated into a single score. Further weighting of these last results was then made for size of organization represented by the respondent, with weights of unity and 2 assigned respectively to organizations with under 10, and with 10 and over, engineers. Accordingly, 3 sets of results were obtained. When these were compared, a few minor differences in the popularity position of some line items were noted but, in gen-

eral, close agreement existed between the 3 sets of results. For this reason, data from only the middle procedure—*Weighting According to Degree of Essentiality*, are presented in the remainder of this article. These have been converted to a percentage scale, with 100 representing the highest possible score.

COMPARISON BETWEEN BASIC SCIENCE, APPLIED THEORETICAL, AND APPLIED TECHNICAL SUBJECTS

For simplification, this comparison

ignores several other classes of subjects.

In general, the trend of responses was away from applied theory, i.e., intermediate subjects, toward the poles of basic science and practice.

This can be illustrated by comparing the most popular basic science course (bacteriology) with certain water supply subjects, since this was the most popular field of sanitation. The basic science subject of *Elementary Bacteriology* and the applied technico-administrative subject of *Public Health Super-*

vision and Inspection of Water Supply Systems were tied for first place, with a score of 96 per cent. By contrast, the intermediate subjects of *Review of Water Treatment Plant Design* and of *Water Laboratory in Sanitary Chemistry* were in 6th and 9th places, with scores of 79 per cent and 73 per cent.

The total number of 89 line items reduced themselves to 49 positions of rank, due to numerous tied scores, with the median position of 25 having a score of 55 per cent. While *Elementary Bacteriology* had a higher position than any other so-called basic science course, others ranked favorably. *General Epidemiology*, which many consider a basic science in the applied profession of public health, was in 13th place, with a score of 70 per cent. *Applied Epidemiology of Milk-borne Diseases* was 17th, with a score of 63 per cent. *Elementary Biology*, *Applied Elementary Entomology of Disease Transmitting Insects* and *Epidemiology of Murine Typhus* were at or slightly above the median, as was also *Hydrology*. *Elementary Parasitology* was slightly below the median. Although several of these subjects are

applied in character, they possess a basic science significance when considered in a curriculum for public health engineers.

COMPARISON BETWEEN FIELDS OF SANITATION

The order of popularity of 17 fields of sanitation is shown in Table 1. This was determined by selecting the most popular line item subject in each field and assigning its position of rank to the field in which it belonged. The number of fields of sanitation as conventionally recognized is expanded; in part because the subjects Rural Sanitation and Plumbing were given separate status due to difficulty of placement.

MOST POPULAR SUBJECTS

In Table 2 are listed the 20 most popular subjects in order of position. As mentioned previously, some of these are elements rather than course entities.

COMPARISON BETWEEN STATE AND LOCAL RESPONSES

Due to the small size of the "Local Health Department" sample (8 replies),

TABLE 1
Comparison Between Fields of Sanitation

| Field | Rank | Score, Per cent | Field | Rank | Score, Per cent |
|-----------------------------------|------|--------------------|--------------------------------------|------|--------------------|

results may not be fully significant. Furthermore, rural areas were not represented; the responding units consisting of large cities or city-county departments in congested metropolitan areas. Table 3 lists the 20 most popular subjects, tabulated separately for state and local responses. (Twenty-two are listed, because 3 subjects are tied for 20th place).

The outstanding differences between the two lists are the greater spread of subject content, and the greater interest in administrative and so-called "public health" subjects, demonstrated by the local respondents. Considering the upper half of Table 3 first, *i.e.*, the first 11 subjects, 8 subjects in the *State* list are in the fields of water and sewerage. Four of these are in design and laboratory phases. Only 4 general classifications are represented—*water, sewerage, basic science, and rodent control*—as compared with 6 in the *Local* list—*basic science, water, bathing, food, milk, and basic public health*.

The number of *water* and *sewer-*

age courses is reduced from 8 to 1 in the *Local* list. Three so-called public health courses are in the *Local* list, but none in the *State* list. These are: *General Epidemiology, Epidemiology of Food-borne Diseases* and *Public Health Administration*. The most popular field of sanitation in the *Local* list is *Food Sanitation*, which placed 3 subject elements in the first 11 items.

The differences cited above do not change appreciably when the entire 22 items are compared. The *Local* list is more comprehensive, more concerned with administration, epidemiologic principles, basic science and operating practices and less concerned with design and laboratory courses, even where these are of a review character.

Superficially, the marked differences in the two lists is surprising, since a letter accompanying the form requested its completion on a basis of training needs for all public health engineers supervised by the reporting office. Hence, state office reports presumably included the needs of many local engineers and

of district engineers engaged in local types of service. The principal explanation appears to be that many states even today do not yet have a fully developed program of local health service, while local populations in some others are too small to warrant establishing local engineering positions in significant numbers.

Which of the two lists offers the more fundamental training rests on the personal opinion, and in some cases prejudices, of the individual. It is apparent however, that state opinion tends toward the technician and the specialist, while local opinion favors training engineers to be technical administrators. That this division of opinion is far from being clear-cut however, may be illustrated by the following comment from

one respondent who has directed a state bureau of engineering for the past 25 years:

"I think the right track is to endeavor to develop a course more suitable for the rank and file of public health engineers. I believe these men should have a broader training in general public health activities rather than too much specialization in a few phases of the profession. It has been my observation that certain men should have specialized training who will be on specialized phases of activities, but that the majority of the men in the average health department will be required to cover more than one field of activity. Particularly is this true of those men who will go into local health services."

Cutter Lecture at Harvard

The Harvard School of Public Health announces that William N. Pickles, M.D., Medical Officer of Health, Aysgarth Rural District, Yorkshire, England, will deliver the Cutter Lecture on Preventive Medicine. April 12, 1948, 5 p.m. in Amphitheatre D of the Harvard Medical School. His subject will be "Epidemiology in Country Practice."

The Cutter Lectures have been held since 1912, according to the terms of the will of Dr. John Clarence Cutter, of the class of 1877, which directed that they should be "free to the medical profession and to the press." In addition, medical and public health students and others interested are cordially invited to attend.

Bacteriological Studies of the Fort Loudoun Reservoir*

ROBERT N. CLARK, F.A.P.H.A., AND
F. W. KITTRELL, F.A.P.H.A.

Tennessee Valley Authority, Chattanooga, Tenn.

FORT Loudoun Reservoir is one of the nine TVA reservoirs in the main channel of the Tennessee River. It extends from Fort Loudoun Dam at river mile 602.3 to a point above Knoxville, the limits of which extend from mile 641 to 651. The accessibility of the reservoir to a large population center emphasizes its potentialities as a recreation area, so when a general study was made of the quality of the water in the reservoir, particular attention was given to bacteriological investigations. The present discussion deals almost solely with an analysis of the factors which influence the density of coliform organisms, and consequently which affect the suitability of water in different parts of the reservoir for bathing.

It is important to understand that the Tennessee River is formed by the confluence of the Holston and French Broad Rivers, immediately above Knoxville, and that there is a deep storage reservoir on each of these two tributaries impounded by Cherokee Dam 52 miles above the mouth of the Holston, and Douglas Dam 32 miles above the mouth of the French Broad. During the bathing season the water passing both of these dams is drawn from the bottoms of the reservoirs through the turbines and is consequently very cold.

Cherokee and Douglas Reservoirs provide storage capacity enough to protect the streams below the dams from the effects of upstream pollution. Below Cherokee Dam, the Holston River receives septic tank effluent from a sewered population of 2,500 at Mascot, Tenn., and raw sewage from the Burlington section of Knoxville, with a sewered population of 5,300. Below Douglas Dam, the French Broad River receives raw sewage through the Little Pigeon River from Sevierville, Tenn., with a sewered population of 460. At Knoxville, raw sewage is discharged into the reservoir from a population, exclusive of the Burlington section, of 86,800. The effluent of a primary sewage treatment plant from Maryville, with a sewered population of 5,800, and the effluent from a secondary treatment plant at Alcoa with a sewered population of 4,600, enter the reservoir through Pistol Creek and Little River. All sewered population data are of 1940, and the loads were doubtless greater in 1944 when the reservoir study was made.

Sampling stations were chosen with two purposes in mind, first to reveal the quality of water adjacent to potential swimming areas, second to show the course of bacterial pollution in the main channel of the reservoir. Accordingly, 21 stations were chosen along the shoreline, some on the main reservoir and some on embayments, and 14 stations were established in the main channel. Three of the latter were above Knox-

* Presented at a Joint Session of the Conference of Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

ville, 2 were within the city limits, and the remaining 9 were spaced at intervals of about 5 miles downstream to Fort Loudoun Dam. Sample collections were made by boat. The swimming area samples were all collected from a single point at the surface. Main channel samples were collected at 3 points equally spaced across the reservoir. From June 28 to July 19, all channel samples were taken from the surface, and from then until October 2 all channel stations were sampled at mid-depth. Surface samples were collected in sterile bottles at a depth of 4 to 6 inches below the surface, with a forward scooping motion. Depth samples were collected in a device that permitted opening and closing the sample bottle at any desired depth. All samples were iced from the time of collection until delivery to the laboratory. The maximum time between sample collection and the start of bacteriological examination rarely exceeded 6 hours.

Laboratory examinations were made in accordance with *Standard Methods for the Examination of Water and Sewage*. Four tubes of each of at least 4 dilutions were inoculated in lactose broth. The presumptive tests were confirmed by transfer to brilliant green bile tubes from all 4 lactose tubes of the highest dilution in which all tubes showed gas, plus any tubes in higher dilutions showing gas. The three samples from the quarter points of each channel station were composited in equal portions in the laboratory, and examination was made of the composite sample.

An essential part of the study was the correlation of hydraulic data with the sampling schedules. Times of water travel between stations were computed from observations of stream discharge and channel measurements, with due consideration of stratification, temperature, and reservoir operation, as well as the effect of other natural phenomena, and the times were field-checked by

chemical methods. Stream discharge data and reservoir elevations were secured from records of the TVA and Water Resources Branch of the Geological Survey.

Valuable information on raw water temperatures and the densities of coliform organisms in the water above Knoxville, compiled daily and extending over a period of two years, was secured from the operation reports of the Williams Creek Filtration Plant of the Knoxville Electric Power and Water Board. Records prior to 1943 were not used, since impoundage of Douglas Reservoir in February and March, 1943, caused a marked reduction in the numbers of coliform organisms contributed by the French Broad River.

The principal factors to be considered in an analysis of coliform densities at various points in a river are the total number of organisms reaching the stream, the rate at which such organisms are reduced, and the time of water travel between the points in question. Other elements to be considered in Fort Loudoun Reservoir are variations at different points in a single cross-section, effects of side pollution, rainfall, wave action, density currents, and diffusion in embayments, and stratification.

The concentration of coliform organisms at river mile 645.5, which is about 1.7 miles below the center of gravity of sewage discharge from Knoxville, depends upon the number of organisms in the water above Knoxville, the number of organisms contributed by Knoxville sewage, and the dilution afforded by the river discharge. Records of the water plant were investigated for the May through September periods of 1943 and 1944, and the data obtained were correlated with stream discharge data. It was found that the total number of organisms carried past the water works intake each day was almost constant. Assuming a constant daily contribution from Knoxville sewage, this means that

FIGURE 1—Average Coliform Values at Sampling Stations

for practical purposes the total number of coliforms passing mile 645.5 may be considered constant, and the coliform density may be considered inversely proportional to the river discharge. It was found that the average number of coliforms in the river above Knoxville was 0.228×10^{15} , and at mile 645.5 it was 7.563×10^{15} .

A comparison was made of observed data on coliform densities in main channel samples between those collected at the surface and those at mid-depth, also with surface samples collected along the shore and in embayments. This comparison is shown in Figure 1. Sampling points in embayments are plotted against the river mile at the mouth of the embayment. On this figure, the coliform values obtained on samples other than from the river channel indicate consistently low concentrations. In only one case the MPN per 100 ml. exceed 300, and that was a point

at mile 633.3 on the exposed right bank of the main river.

An analysis of the two curves plotted for surface samples and for mid-depth samples from the channel stations reveals an important relationship. From Knoxville downstream to about mile 630, the coliform densities at the surface and at mid-depth are in quite close agreement. Below this point, however, there occurs a sudden and wide divergence with a much lower density of organisms at the surface than at mid-depth. This is explained by stratification in the reservoir. An idealized diagram of this condition is shown in Figure 2. It has been noted previously that releases from Cherokee and Douglas Reservoirs are at very low temperatures, and during the summer when surface temperatures in Fort Loudoun Reservoir are comparatively high, the denser cold water flows along the bottom, leaving the surface stratum relatively undis-

turbed. During the period from May through July, the temperature difference between the epilimnion and the hypolimnion remained fairly constant at about 8°C . In August, the difference dropped to about 5°C . and in September to about 2°C . There was a definite tendency in the stratified section for coliform densities at the surface to exceed average values during the latter part of August and in September. This may have been due in part to wind action, since available records indicate more wind movement during this period. It is believed that the lower temperature differentials, which reduce the sharpness of stratifications, were responsible for most of the observed tendency.

Numerous field observations revealed that during the summer the cold water from upstream occupies the entire cross-section of the reservoir at Knoxville and for a variable distance downstream. Under various combinations of density and discharge, the flowing water does not require the entire cross-section of the

channel near the lower end of the reservoir, and leaves the surface stratum undisturbed. Increased discharge rates cause the flowing water to occupy correspondingly larger portions of the cross-section and, in effect, force the upper end of the zone of stratification downstream. A decrease in the temperature differential between the surface and bottom has an equivalent effect. As these factors vary, the quiescent, and relatively unpolluted epilimnion may expand, contract, or disappear altogether. It is estimated that with the temperature differentials prevailing during the summer, the epilimnion will be completely eliminated by discharges in May through July of 28,000 cubic feet per second (c.f.s.), in August of 24,000 c.f.s., and in September of 17,000 c.f.s.

By similar analysis, the location of the upper end of the stratified section can be estimated for any condition of discharge and temperature. It may be expected that the coliform densities in surface samples collected upstream from

FIGURE 2—Diagram of Stratification

FIGURE 3—Coliform Organism Death Rate Curve

the stratified zone will be of the same order as samples collected at mid-depth, but that surface samples collected from points downstream from the upper limit of the stratified zone will be from the epilimnion, and will be less polluted than mid-depth samples.

An investigation was made of the death rates of coliform organisms using the method described by Frost and Streeter¹ applied to the data obtained on mid-depth samples. The times of water travel were computed for each sampling date and each sampling station by the Hydraulic Data Division of the TVA, and are believed to be unusually accurate for a study of this kind. Data on average coliform densities were reduced to percentages of the value at mile 645.5, and these percentages were plotted against time as indicated in Figure 3. The theoretical formula was computed as $y = 96.8 (10^{-0.5158x}) + 3.20 (10^{-0.0912x})$. Using the derived formula, the expected coliform density after

any given period can be computed as water travels downstream from Knoxville.

An evaluation of these factors, namely, total coliform load, time of water travel, discharge, and position of the upstream limit of the stratified section, is shown in Figure 4, in which coliform densities, estimated from death rate formulae, are plotted against time of water travel for several river discharge rates. Also plotted, in dotted lines, are the river miles corresponding to given time of water travel for each discharge rate below mile 645.5. Finally, the location of the upper end of the stratified section is plotted for each rate of stream discharge. From this and similar charts prepared for other months, it is possible to estimate the probable coliform density at any point in the moving water in the main river channel for various discharges and temperature differentials.

Some study was made of observations

FIGURE 4—Diagram of Estimated Coliform Densities, September

on embayment stations to determine what correlations might exist between coliform numbers and distances away from the main river channel. It was found that above the limits of the stratified zone, all embayment samples showed significantly lower coliform numbers than were found in the channel. In the stratified zone, the coliform densities at the surface were about the same in the epilimnion and in the embayment, with a definite trend toward higher numbers at stations more distant from the channel. This may be due to the increasing effect of shore pollution as the cross-section of the embayment decreases toward its head, or it is more likely due to the effect of density currents. Such currents were not measured during this study, but have been observed under similar conditions to flow up an embayment on the bottom and down the embayment in a surface counter-current. The phenomenon is

due to surface warming, with consequent changes in water density.

The effect of rainfall and surface wash was also examined by grouping data by ranges in rainfall of 0.1 to 0.30, 0.31 to 0.60, and over 0.60 inch, and also by the number of days the sampling dates followed rainfall. No effect was observed from rainstorms of 0.60 or less; but, following higher rainfalls, the coliform values exceeded the average on the day of precipitation and for one day following. These conclusions are based on a summary of data from all stations, since the data available from a single station were not adequate to justify a correlation. One storm of unusual magnitude occurred at the end of September throughout the reservoir drainage area. Seven rain-gage stations in the vicinity of the reservoir reported total rainfalls for the two day storm ranging from 5.14 to 8.80 inches, with an average for the seven stations of 6.56

inches. On October 2, two days after the storm, samples were collected from several stations, and the coliform densities are shown in Figure 5 where the results of this one sampling are plotted, with the average of samples collected on all other days. All of the results shown in this figure are on samples collected from embayment stations. The possibility was investigated that factors other than run-off, such as disturbance of stratification, may have exerted an influence on these results, but it was concluded that the abnormal run-off was the principal cause of the excessively high values. This incident is recognized as an example of the degree of pollution to which even the best of surface waters occasionally may be subjected.

One of the reasons for undertaking the bacteriological study of Fort Loudoun Reservoir was to assess the effect of Knoxville sewage on potential bathing areas. Since the pollution is clearly of sewage origin, the Tennessee Department of Public Health will not approve

the development of public bathing facilities in the reservoir unless the most probable number (MPN) of coliform organisms per 100 ml. is 50 or less, in keeping with the definition of Class A bathing waters accepted by the seven Tennessee Valley states. A study of the probability of river discharges of certain magnitudes reveals that MPN's greater than the allowed maximum will occur frequently during the season from May through September; and, consequently, the Class A standard cannot be met with certainty at any point in the reservoir during the bathing season. Under existing conditions, therefore, no public bathing developments can be permitted or approved.

Aside from the recreational aspect, the Fort Loudoun study provides an interesting evaluation of the self-purification capacity of a large reservoir as it affects the bacteriological quality of the water. Such data are useful in estimating the effect of treatment or, conversely, the degree of sewage treatment required

FIGURE 5—Effect of Severe Rainstorm on Coliform Numbers

FIGURE 6—Estimate of Effect of Sewage Treatment

under a given set of conditions. At the present time, the City of Knoxville is planning sewage treatment works and has engaged consulting engineers to design the necessary facilities. An estimate of the possible effect of treatment on the bacterial quality of the water below Knoxville is shown in Figure 6. In order to present the conditions which would obtain for a large share of the time, the chart has been prepared for flows which probably will not be exceeded more than 5 per cent of the time during the month of August. This month has been chosen, since the stream flow conditions and the probability of high flows during August are generally typical of the conditions throughout the summer. The estimated effect of treatment is based on a reduction in coliform organisms of 50 per cent for primary treatment, and 98 per cent for primary treatment and chlorination.

Several possible effects have not been

included in the computations for this chart. Although the calculated reductions due to treatment have allowed for the organisms in the stream passing the water works intake, they do not include the consideration that some sewage from Knoxville discharged above that point may be treated. Neither do they allow for sewage entering the river below mile 645.5, which may likewise be treated. Another factor to consider is that the computations have been based on a center of gravity of sewage discharge at mile 647.2, while the present plans contemplate a treatment plant and outfall some distance below this point. This chart should be considered, therefore, as being only an indication of the anticipated effect of treatment.

The basic information in this paper is taken from a report² by the Stream Sanitation Staff of the Tennessee Valley Authority, prepared under the direction of G. R. Scott. The field and laboratory

work incident to the study and the major share of preparing the report were carried out under the immediate supervision of F. W. Kittrell, now in charge of stream sanitation work of the TVA.

Fellowships in Public Health Education

The National Foundation for Infantile Paralysis is providing for 1 year graduate training fellowships in public health education leading to a Master's degree to fill vacancies in state and local health departments. Men and women between the ages of 22 and 40 inclusive, who are not now employees of such departments, will be accepted.

Candidates must have a Bachelor's degree, plus 3 years of professional experience or its equivalent, and must agree to complete satisfactorily a year's academic work and 3 months of field training, and must agree to accept employment in the field of public health education in the United States for at least two years. Fellowships will be given for training only in schools of public health which have curricula in health education and which are accredited by the American Public Health Association.

Applications should be made to the Credential Secretary of the National Foundation for Infantile Paralysis (120 Broadway, New York 5). When all credentials are complete and the candidate has been accepted by a school, the application will be submitted to the Public Health Fellowship Awards Committee, an advisory subcommittee of the Public Health Service Committee on Training of Public Health Personnel. This Committee is made up of representatives of the U. S. Public Health Service, U. S. Office of Education, and professional public health educators. Its decision on applicants will be accepted as final by the Foundation.

Beginning in March, the Committee is meeting at approximately monthly intervals until the schools open in the fall or until all the fellowships have been awarded. Applications should therefore be made as early as possible.

Specific Complement-Fixing Diagnostic Antigens for Viral and Rickettsial Diseases*

HERALD R. COX, Sc.D.

*Section of Viral and Rickettsial Research,
Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.*

IT is now generally accepted that the complement-fixation test is a highly useful method of carrying out diagnostic tests for various viral and rickettsial infections. The antigens for diagnosis of viral infections described by Frobisher,¹ Howitt,^{2,3} Casals and Palacios,⁴ Casals,⁵⁻⁸ Lennette and Perlowagora,⁹ and Havens and his associates¹⁰ were prepared almost entirely from infected brain tissues, whereas those reported by Mohler¹¹ and Brown¹² were prepared from infected chick embryo tissues.

Various procedures, such as ether extraction,³ repeated freezing and thawing followed by centrifugation,⁴ and fractional centrifugation at speeds as high as 12,400 r.p.m. for one hour¹⁰ were used in attempts to eliminate the anti-complementary and nonspecific properties of the preparations. Such measures were not too satisfactory, however, and this was found to be especially true when the antigens were tested in the presence of strongly positive syphilitic human sera,^{4,9,13,14} in which case markedly false positive reactions occurred. Similar observations were reported by Wertman¹⁵ who found crude rickettsial antigens prepared by methods suggested by Bengtson^{16,17} and Reynolds and Pol-

lard¹⁸ to give markedly nonspecific fixation of complement with syphilitic sera. To overcome these difficulties with neurotropic viral antigens prepared from infected brain tissues, Casals and Palacios⁴ recommended that Wassermann-negative human sera be inactivated at 60° C. for 20 minutes, whereas Wassermann-positive sera should be inactivated at 65° C. for 20 minutes. Similarly, Brown¹⁹ has recently suggested that sera to be used with chick-embryo eastern and western equine encephalomyelitis antigens should be inactivated at 60° C. for 15 minutes in order to eliminate nonspecific reactions. Wertman¹⁵ overcame the difficulty by using washed rickettsial or elementary body antigens for the diagnosis of rickettsial or psittacosis-lymphogranuloma-venerum infections. These latter antigens were found not to give rise to false positive reactions even when the more sensitive technique of 18 hours of fixation in the cold was used.

Inasmuch as in recent years antigens derived from infected chick embryo and mouse brain have been used on an ever increasing scale in the diagnosis of viral and rickettsial diseases, it was deemed worth while to reinvestigate these preparations for their specificity, especially with syphilitic and malarial sera. The investigations were purposely directed at the mode of preparation of the antigens themselves, because it was felt that

a dependable and practical procedure for the preparation of truly specific antigens would be a worth while contribution in itself, and that, furthermore, additional information might well be gained concerning the essential properties of the various infectious agents involved. For the sake of clarity, the data pertaining to the viral and rickettsial antigens will be dealt with separately.

VIRAL ANTIGENS

In preliminary experiments carried out by DeBoer and Cox¹⁴ with antigens prepared essentially by the method of Casals and Palacios,⁴ it was found that when chick embryo antigens were tested against homologous immune guinea pig sera or when mouse brain antigens were tested against homologous immune mouse sera, no cross-reactions occurred. However, both types of antigens were found to be not truly specific because they fixed complement with known positive human syphilitic sera, when the latter were inactivated at 56° C. for 30 minutes.

Table 1 shows the results obtained with chick embryo antigens of the above mentioned type. Notice the lack of specificity of these antigens in the presence of a positive syphilitic serum.

Table 2 shows the lack of specificity of similarly prepared mouse brain antigens when they were tested against 2 syphilitic sera.

The suggestion of Casals and Palacios,⁴ namely, to heat the sera under test at a higher temperature in order to

eliminate or minimize the nonspecific reactions, was next investigated. However, it was found that higher temperatures, though they did not greatly reduce the titer for western equine encephalomyelitis antibodies in immune sera, did almost invariably reduce them for rabies, Colorado tick fever, and St. Louis encephalitis viruses to a very significant degree. The same was found by Hughes²⁰ to be true for the antibodies against yellow fever virus, since they too are particularly heatable. In many sera where the antibody titers initially are quite low, such as have been encountered particularly with rabies and Colorado tick fever antisera, it is not possible to inactivate these sera at temperatures in excess of 56° C. without rendering them unfit for testing.

Tables 3 and 4 show the effects of the inactivation temperature on the complement-fixation titers of human sera following Colorado tick fever infection and antirabic vaccination, respectively. In both instances, at least a twofold loss in titer occurred when the sera were inactivated at 60° C. for 15 minutes, as was suggested by Brown.¹⁰ In fact, the antibody titers of antirabic vaccination sera are so low that it is difficult to demonstrate antibodies even though the tests are carried out under the most favorable conditions, that is, inactivation of the sera at 56° C. for 30 minutes and using 1½ units of complement instead of 2.

Influenced by these findings and encouraged by the results obtained by

Wolfe, van der Scheer, Clancy, and Cox²¹ with rickettsial antigens, using a procedure similar to that of Cragie and Tulloch,²² and Howitt,^{2, 3} it was decided to test antigens that were prepared by extracting them in the lyophilized state with various solvents. It was found that antigens for eastern and western equine viruses prepared from infected embryos and for eastern equine, western equine, St. Louis, and Jap B viruses, prepared from infected mouse brains, are rendered specific without appreciable loss in antigenicity, by extraction in the lyophilized state with benzene, toluene, or ethylene-dichloride.¹⁴ At this point it may be worth while to note that tests made with antigens of chick embryo origin for St. Louis and Jap B were not too satisfactory in spite of the fact that infective titers of 10⁻⁷ and 10^{-6.6} or higher, were achieved for these viruses respectively. The antigens were specific inasmuch as they fixed complement only in the presence of their homologous immune sera and did not produce false positive reactions with human syphilitic or malarial sera when the method of Kolmer and Boerner²³ was employed. The antigens so prepared were also quite stable and noninfectious.

Table 5 summarizes some of the results obtained with lyophilized and benzene-extracted chick embryo antigens of

eastern and western equine encephalomyelitis, as well as a normal chick embryo preparation similarly processed and tested against eastern equine, western equine, and normal guinea pig sera, and a syphilitic human serum. It is seen that the viral antigens showed positive fixation only in the presence of their homologous antisera.

Table 6 shows the results obtained with lyophilized and benzene-extracted mouse brain antigens of eastern equine, western equine, St. Louis, and Jap B viruses when tested against two known highly positive syphilitic sera. A control antigen prepared from normal noninfected mouse brains is also included. It is noted that none of the mouse brain preparations showed a positive fixation in the presence of the syphilitic sera.

Table 7 shows the results of complement-fixation tests with lyophilized and benzene-extracted mouse brain antigens against normal and immune mouse sera.

The results indicate complete specificity of both the eastern equine and western equine antigens against all sera tested, while the St. Louis and Jap B antigens showed slight cross-reactions against each other only. These observations are in accord with the findings of Casals and Palacios.⁴

In a subsequent report by DeBoer

and colleagues,²⁴ it was shown that specific diagnostic antigens for Colorado tick fever could be prepared similarly by benzene extraction of desiccated mouse brains infected with this virus. Cross-fixation tests between Colorado tick fever immune sera and various heterologous antigens of viral and rickettsial origin indicated that Colorado tick fever is a distinct entity and not related to any of the other infectious agents tested. Close correlation was obtained in the complement-fixation and mouse neutralization tests with human convalescent sera. The complement-fixing and neutralizing antibodies appeared in the blood of human patients at about the 9th to 14th day after onset of illness and remained demonstrable for as long as 34 months.

At the same time that DeBoer and Cox¹⁴ reported their work on benzene-extracted antigens, a comparable study along the same lines was published by Perlowagora and Hughes.¹³ These workers prepared specific complement-fixing

antigens for yellow fever virus by extracting desiccated infected mouse brains with ethyl ether in a Soxhlet apparatus until they were lipid free. The anhydrous and lipid-free tissues were then resuspended in 0.9 per cent sodium chloride solution and the globulin fraction precipitated by one-half saturated ammonium sulfate solution. The washed and purified globulin fraction used as antigen was found to be highly sensitive and specific.

RICKETTSIAL ANTIGENS

As mentioned above, Wertman¹⁵ used washed and "purified" rickettsial body antigens, prepared by the method of Plotz²⁵ and his colleagues²⁶⁻²⁸ to overcome the nonspecific fixation results encountered in using the cruder preparations. However, the preparation of washed rickettsial body antigens is a rather laborious and costly procedure and especially difficult in the case of rickettsiae of the spotted fever group, since they do not grow as profusely as

* Rocky Mountain Spotted Fever Convalescent Guinea Pig Serum.

do the rickettsiae of the typhus, scrub typhus, and Q fever groups.

In a recent publication van der Scheer, Bohnel, and Cox²⁰ confirmed the findings of Wertman¹⁵ that epidemic typhus, murine typhus, and Rocky Mountain spotted fever vaccines, prepared from infected yolk sacs by ether-extraction in the fluid state and used as antigens, give nonspecific reactions in complement-fixation tests with positive syphilitic sera—especially if the technic of fixation for 18 hours in the cold is used. However, they showed that purified and concentrated *soluble antigens* could be prepared from epidemic typhus, murine typhus, and Rocky Mountain spotted fever vaccines by further treating the ether-extracted preparations with benzene followed by precipitation with sodium sulfate. The resulting purified *soluble antigens* gave little or no reaction with highly positive syphilitic sera using fixation of complement at icebox temperature for 18 hours. Tests carried out with the concentrated and purified *soluble antigens* clearly differentiate cases of epidemic and murine typhus from Rocky Mountain spotted fever and will often, but not always, distinguish between epidemic and murine typhus cases. Strong cross-reactions were also observed in tests made with epidemic and murine typhus human sera and corresponding purified and washed rickettsial body suspensions prepared by the method of Plotz and colleagues,²⁸ but in these cases the titer obtained was always higher with the homologous than with the heterologous rickettsial antigens.

Table 8 shows the results of complement-fixation tests by the method of Kolmer and Boerner with human syphilitic sera and Rocky Mountain spotted fever *soluble antigens* Nos. 1 and 2, prepared by sodium-sulfate precipitation of vaccine with and without previous extraction with benzene. It is seen

that four of the sera gave a 4+ reaction in the 1:4 dilution with the non-benzene-extracted antigen, but that the same sera gave reactions of only 1+, 2+ and 3+ in the 1:4 dilution with the benzene extracted antigen.

CONCLUSION

In conclusion, it is seen that methods are now available for the preparation of highly sensitive and specific complement-fixing antigens in an ever increasing number for the diagnosis of viral and rickettsial diseases. Specific diagnostic antigens that have been prepared in our laboratory up to the present are: *Viral antigens*: eastern equine, western equine, St. Louis encephalitis, rabies, Colorado tick fever, influenza types A and B, mumps, and psittacosis; *Rickettsial antigens*: epidemic typhus, murine typhus, scrub typhus or tsutsugamushi disease, Rocky Mountain spotted fever, Q fever, and rickettsialpox.

Experience in Appraising Nutritional Status in the U. S. Public Health Service*

HAROLD R. SANDSTEAD, M.D., F.A.P.H.A., AND
ELTON S. OSBORNE, JR., M.D.

*Chief, Nutrition Section, States Relations Division, U. S. Public Health Service,
Washington, D. C.; and Medical Officer in Charge of Nutrition Field Unit,
Grand Haven, Mich.*

FOR a number of years, various official and voluntary agencies have been working toward improving the nutritional status of the population. In 1945, the Conference of State and Territorial Health Officers requested that the Service further assist the states in developing nutritional programs. As a result of this Conference, a Nutrition Section in the States Relations Division of the Bureau of State Services was organized.

Since its inception, the basic purpose of this Service program has been to conduct field studies in the prevalence of nutritional deficiency disease to develop methods for assessing human nutrition that can be adopted by health departments, and to provide a pattern which can be utilized by state and local health departments to increase the efficiency of their public health nutrition programs.

The interest of the states in nutrition work has been demonstrated by the fact that within the past two years, 32 state and territorial health departments have requested the services of field units of the U. S. Public Health Serv-

ice. One goal of this program is the active participation of all the state health departments in improving the general health of their populations by promoting better nutrition. Basic programs of this type, organized now, would prove to be of inestimable value in the event of national emergency.

In the opinion of those who organized the Public Health Service Nutrition Section, a prerequisite for an effective program was the obtaining of accurate information on the prevalence of nutritional deficiency disease. Standard methods of procedure for conducting various types of population studies in several sections of the country were thought to be highly desirable in a program of this type. Consequently, mobile field units were created and have been located in four geographic areas in the country—New England, North Central, Mid-Atlantic, and Southeast. To date, thirteen field studies have been completed. These studies were conducted in five states, Florida, Georgia, Maryland, Michigan, and Vermont.

In general, the staff of a nutrition field unit consists of a medical officer in charge, a public health nurse, a nutritionist, a biochemist, a laboratory technician, and a clerk. The personnel of the field unit, however, is occasionally changed to conform with local needs.

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

The existing units have been assigned to work with state health departments on invitation from state health officers after due consideration has been given to the geographic location of the state. These field units, working as a part of the state and local health departments, have carried on the functional part of the program.

As yet, the program has been limited to the investigation and demonstration of nutritional survey techniques. Methods for determining the food patterns of populations and groups within the population have been explored. Evaluation and adaptations of laboratory methods for public health use have been progressing. A large number of persons, approximately 25,000, have been inspected for physical signs of nutritional deficiency, and some therapeutic testing both on individuals and large groups has been conducted.

The Central Office of the Nutrition Section, in addition to its functions of general supervision and coordination of the field units, is developing a program of aid and consultation to state health departments and other agencies interested in nutrition.

Wherever possible, studies have been conducted with the nutrition field unit functioning as a part of a well organized local health department. This arrangement has resulted in the utilization of the local public health nursing staff to contact and invite persons to the survey clinics. Such participation on the part of the local health department develops the interest of its personnel in nutrition and has usually resulted in clinic attendance by the persons invited. When it was not possible to work with a local health department group, it has sometimes been necessary to have the persons to be inspected contacted by a public health nurse or by a nutritionist attached to the nutrition field unit.

All the field studies have followed

the same general plan of operation. The three usual approaches to a nutritional assessment have been used: dietary records, laboratory determinations, and physical inspections.

In the nutrition clinic, consideration for the patient and organizational efficiency are both stressed. Although there are minor variations in procedure among the field units, the following general outline is usually followed: The person attending the clinic is greeted by a receptionist who obtains identifying data, height and weight. A nurse is made responsible for the smooth progression of the patients through the clinic. She routes patients first to the nutritionist, second to the laboratory technician, and finally to the physician. Before the patient departs from the clinic she discusses with him any health problems which have been discovered, with emphasis on arrangements for correction through referral to family physician or health department.

The nutritionist evaluates the diet record and advises the patient about his food habits. The evaluation of diet is based on a system of coding by which the servings of each food group on the diet record can be compared with the National Research Council's¹ recommendations. For the diet record, the patient keeps a complete record of all food taken during a 24 hour period.

In the earlier studies capillary blood from a finger tip puncture was used for the following determinations: hemoglobin, hematocrit, and plasma protein. In more recent appraisals, additional capillary blood has been obtained to use in determining: serum vitamin A, serum carotene, and serum ascorbic acid by the micro-methods of Bessey and Lowry.

On individuals under 16 years of age, blood serum phosphatase is done, and on individuals 40 years or more a blood glucose determination is made, also on capillary blood. The hemo-

globin, hematocrit and plasma protein determinations are usually completed by the technician at the clinic.

The inspection is directed toward the body areas in which signs suggestive of nutritional deficiency are most likely to appear. Such inspections are greatly facilitated by the fact that the signs appear for the most part on exposed areas of the body. After completion of the inspection the medical officer reviews the reports from the nutritionist and the technician; he correlates these data with those obtained in the physical inspection and advises the patient of any obvious health problems which may be evident.

A complete report of the findings on each person is prepared for the local health officer, who usually refers the positive findings to the individual's family physician. In most areas such cases are followed up by the public health nurses until corrections are made. These positive findings are not limited to nutritional deficiency conditions but include any condition needing medical attention which might be discovered during the inspection in the nutrition clinic.

We wish to stress the importance of integrating the nutrition services with the services of other departments. Our experience in the field clinics illustrates this point. During the course of the examination for signs of nutritional deficiencies, numerous physical defects and disabilities other than nutritional are observed. We believe that interest in general health, and not interest in nutrition alone is an important factor in attracting adults to the nutrition clinics. For example, in one study of families, comprising 1,434 individuals, 463 were found to have physical conditions indicating referral for medical consultation. The majority of these individuals were not under the care of physicians and in most instances were unaware of their condition.

As might be expected, many medical problems of interest are revealed at the clinic. For example, in a family study in a mining village 55 per cent of the persons 45 years of age and older had either a systolic blood pressure over 150 mm. Hg. or a diastolic blood pressure over 100.

At this point it should be reemphasized that nutrition is a part of general medicine and in assessing the nutritional status of an individual, influencing factors such as infection, physiological stresses, and disease must be taken into consideration in nutrition evaluation.

The studies which have provided the most complete information regarding the nutritional status of a community, have been of the family type. These surveys have been planned to provide a random sample of an entire population.

In this type of survey, the family, including all members of the same household who eat an average of two meals daily at the same table, is the basic unit. This assures a wide age distribution. The families to be inspected have been selected on a pattern that provides a true random sample of the population.

Usually it has been found advisable to delay the beginning of the family type survey for some time after the field unit moves into a new community. In order to gain the coöperation of the families selected for the survey, some preliminary publicity and other work have been necessary. Consequently, the field unit has frequently first conducted studies of certain special groups, such as school children and industrial workers.

There is no doubt that it is very difficult to impart nutrition education in one clinic visit, but we feel that this one visit is more effective in teaching good nutrition than the usual nutrition propaganda to which we are all subjected.

PREVALENCE OF PHYSICAL SIGNS ASSOCIATED WITH DEFICIENCY DISEASE

In presenting data on the prevalence of physical signs which have been found in these studies, it is recognized that, as in any medical examination, diagnosis on the basis of a single physical sign is hazardous, and that many of these so-called signs are based on too little evidence. One of the greatest needs in nutritional appraisals is a better understanding of the signs and symptoms which have been listed as evidence of deficiency disease. Particularly is this true of the diagnosis of vitamin A deficiency.

For purposes of this report the classifications of signs and symptoms of vitamin deficiencies listed by the Council on Food and Nutrition of the American Medical Association² is followed. Among the conditions that are believed to be associated with nutritional deficiencies are the following: vitamin A deficiencies (folliculosis of the palpebral conjunctiva, thickening of the bulbar conjunctiva and spots, xerosis and follicular hyperkeratosis); vitamin B-complex deficiencies (outer canthi lesions, nasolabial seborrhea, follicular plugs, stomatitis, and glossitis); vitamin C deficiencies (gingivitis, perifollicular petechiae, and purpura). Abnormal response to tests for knee jerks, ankle jerks, and vibratory sense, and calf tenderness may be indicative of neurological changes also due to a deficiency of B-complex.

To allow for all possible inclusions, the Nutrition Appraisal Record used by the field units provides for more than the findings enumerated above. Some of these may be of questionable dietary significance and, when more specific knowledge is acquired, they may eventually be dropped from the list. Others are of infrequent occurrence but highly significant when they do occur.

The Nutrition Appraisal Record has been in use since January, 1946. This

record form pools all the information for one individual (physical inspection in detail, dietary and laboratory data). It is thus now possible to compare the results of one group of school children with another, and one family study with another. The data are fairly comparable because all personnel engaged in the field spend a period of training in one of the units and assist in making a study, before being assigned to work independently.

SCHOOL STUDIES

Slightly more than 1,800 white school children have been examined by the units in the North Central and Mid-Atlantic regions. The school children consisted of those attending (1) grades 4 through 8 in three Maryland schools, (2) the first through the 8th grade in two Maryland schools and one school in Michigan, and (3) high school students in one community in Michigan. There is considerable variation between schools in the same area as well as in different regions. In May, 1946, grade school children were examined in three schools in Maryland and one school in Michigan with a consistently higher prevalence of certain physical findings in Michigan. In the fall of 1946, children were studied in two grade schools in Maryland, and during the winter in a high school in Michigan.

For the more important diagnostic findings, the prevalence in the five school groups was as follows: Forty-seven per cent of the children in the 1st through the 8th grades in the Michigan school and 46 per cent of the high school students had conjunctival folliculosis. Only 2 per cent of children in the combined Maryland Schools study suffered from this condition. In the remaining two Maryland schools the prevalence was 28 per cent and 23 per cent.

Xerosis and follicular hyperkeratosis of the skin were present in 39 per cent

of the children in the 8 grades that constituted the grade school study in Michigan, and 28 per cent of the high school students. In Maryland, the highest prevalence noted in any of the schools studied was 5 per cent for this sign.

One or more tongue conditions were recorded in 12 per cent of the children inspected in one of the school groups in Maryland, 7 per cent in another, and in 8 per cent of the children in the Michigan school group (all 1-8 grades). The prevalence in the remaining grade schools and among high school students was low.

Gingivitis, likewise was high (11 per cent) in one of the Maryland schools (1-8 grades). It ranged from 2 to 6 per cent in the rest of the school groups.

FAMILY STUDIES

To date, six family studies consisting of 3,862 persons have been completed in Florida, Georgia, and Michigan. Another study has been under way in Michigan since April, 1947, and an eighth was started in Vermont during September. One family study was Negro and another partly white and partly Negro. The remaining studies were conducted among white populations.

The prevalence of physical findings in family studies has a different distribution from that among school children. Thickening of the bulbar conjunctiva and spots was the most frequent sign found in Negroes (37 per cent), followed by conjunctival folliculosis (32 per cent), and gingivitis (25 per cent). Among white persons, gingivitis was present in 24 per cent of the population, and thickening of the bulbar conjunctiva and spots in 26 per cent, xerosis and follicular hyperkeratosis in 15.2 per cent and conjunctival folliculosis in 15.1 per cent.

The difference in magnitudes between school and family groups is due to the fact that certain physical conditions change with age. Although the per cent of white persons of all ages with thickening of bulbar conjunctiva and spots was 26, the per cent was less than 1 in children under 13 years of age, 53 per cent for white males 21 years of age and over, and 42 per cent for white females in the same group. Among Negroes, the differences were even more marked: 1 per cent for children under 13, 83 per cent for males and 75 per cent for females 21 years of age and over.

Conjunctival folliculosis, which was the leading physical finding in the school group, was found in 15 per cent

* Based on less than 5 persons

of all white persons studied. It was found in 30 per cent of the children under 13 years but decreased in prevalence with advancing age. Forty-eight per cent of Negro children under 13 years in the family studies were found to be suffering from this condition.

The prevalence of gingivitis increased with age, so that for adult white males the figure was 59 per cent, for females, 38 per cent, against the averages for all ages of 27 per cent. Comparative figures for Negroes were 62 per cent, 46 per cent, and 25 per cent.

Table 2 shows the prevalence of enlarged thyroid in family and school groups studied from October, 1945, through May, 1947. The prevalence for females at all ages combined was higher than for males in all groups. In most instances the prevalence was greater among adults than among children.

The highest percentages were found in the Michigan groups. In the family study, 48 per cent of females 21 years of age and over had an enlarged thyroid. Among high school students in Holland, Mich., 52 per cent of the girls and 32 per cent of the boys showed this condition.

Table 3 shows the prevalence of signs suggestive of rickets in the same groups of persons who were presented in Table 2. Signs of rickets were, in general, more prevalent among males than females in those groups in which the condition was of frequent occurrence. The prevalence was higher in children and young adults than in older persons.

Among boys under 13 years of age, the highest proportion (41 per cent) occurred in a white family study in Georgia. In a Michigan grade school in which the economic level was low, 61 per cent of the boys over 13 years of age showed signs of rickets. In certain studies, there were few evidences of this condition.

What conclusions can be made from these data? The physical signs attributable to vitamin A deficiency are very prevalent. If these are reliable signs, then vitamin A deficiency is a major problem, at least in the areas where these studies have been made. Additional studies are needed before final conclusions can be drawn.

Next in the order of prevalence is gingivitis. If this represents vitamin C deficiency, it is a major problem in this country. However, we still lack controlled studies demonstrating what percentage of this is related to C deficiency and what percentage is caused by other factors.

Although there are other causes of glossitis it is our impression that this is a fairly reliable sign of B-complex deficiency. If the prevalence of this sign is a good index of B-complex deficiency, then this too constitutes a major public health problem.

Two conditions for which we have for some time had the knowledge for prevention and control are endemic goiter and rickets. Both of these conditions are found with considerable prevalence and represent major health problems which should be the object of continuous attack by the medical profession and health departments.

Fortunately, because we do not have the emergency of actual starvation or serious food shortages seen in much of the rest of the world, our health officials have the opportunity for carefully considered long-range programs in public health nutrition.

Considerable thought, based on field experience, has been given to the development of an administrative pattern for more comprehensive nutrition programs in state and local health departments.

The following pattern, which provides for a division of functions between state and local health departments, is being recommended to state health departments:

A. At the state health department level, facilities and services are suggested which would be financially impractical for the average local health department. These include:

1. Establishment of the nucleus of a nutritional epidemiological unit. At first this may consist only of a physician and a nutritionist with knowledge of appraisal procedures. They could conduct surveys and resurveys of various population groups to determine the prevalence of nutritional problems, and to promote local interest in nutrition. It would be necessary for the local area to assist with personnel in such surveys. Local nursing and clerical assistance would be needed along with the services of a state district nutritionist. Later, a division of public health nutrition, with a physician as its director, would probably evolve. State health departments already are employing nutritionists, who will continue to play an important role in any expanding nutrition program.

2. Provision of laboratory facilities in the state health department laboratory to serve the nutrition epidemiological unit mentioned in A, 1. These laboratory facilities should also be available to hospitals and local health departments throughout the state. Although these facilities would at first have to be made available only to institutions that were equipped to collect and prepare specimens for transportation, they would be offered to all institutions and to all licensed physicians as soon as more practical methods of

preserving specimens for transporting are developed.

B. At the local health department level the following activities would probably be practical in average size departments with jurisdiction over populations of 50,000 or more.

1. Employment of a public health nutritionist to work continually with and through the public health nurses to promote improved nutrition in the local population. This nutritionist would conduct continuous inservice training in nutrition for the local public health nurses. She could prepare special diets for patients on a physician's prescription. She would assist public institutions which do not have a trained dietitian, cooperate with welfare agencies in preparing low income diets, participate in and guide promotional and educational programs in nutrition, and work closely with all types of clinics operated by the health department.

In any such program it is well to emphasize again that nutrition work should be well integrated with other functions of the state and local health departments. In planning this program we must not be discouraged because of shortage of trained personnel, and laboratory facilities. It must be remembered that no public health program was ever initiated under ideal circumstances.

Appraising the Nutritional Status of Mothers and Infants*

CLEMENT A. SMITH, M.D., AND
HAROLD C. STUART, M.D., F.A.P.H.A.

Boston Lying-in and Children's Hospitals; and Department of Maternal and Child Health, Harvard School of Public Health, Department of Pediatrics, Harvard Medical School, Boston, Mass.†

DR. Stuart and I have interpreted the title which we have been assigned on this program to refer to the appraisal of the individual mother and infant from the standpoint of recognizing general malnutrition or specific deficiencies in nutritional status. This is a very different and more difficult problem than that of assessing populations of mothers and infants from the standpoint of the incidence of nonspecific signs and symptoms and events which are known to be highly correlated with faulty maternal diet.

The finding that a new-born infant is very short or very light in weight does not justify the assumption that his mother's diet must have been deficient during pregnancy, for there are many other reasons why he might be small at birth. Group studies of the heights and weights of new-born infants in relation to the adequacy of their mothers' diets, however, justify the assumption that a declining average birth weight and length or an increase in the number of small babies born in a given period of time may well be due to changes in the general level of maternal nutrition during the period. Changes in the incidence

of such conditions as toxemia during pregnancy, stillbirth rates, premature birth rates, and neonatal death rates all justify serious consideration of the nutritional problems which may be involved. This introductory statement is made because in stressing the difficulties of appraising the nutritional status of individual mothers and new-born infants we are not considering the possible usefulness of certain signs and procedures as tools in group studies.

It happens that one of our main research projects illustrates very well the difficulties of the entire subject. Let me state our problem simply. We have, in the Boston Lying-in Hospital, a large supply of clinical material, plus a staff of obstetric and pediatric colleagues as keen and coöperative as might be desired. We have another group of associates able to record and evaluate nutritional histories with the caution and objectivity of long experience. We have facilities and personnel capable of making most laboratory measurements. Yet, faced with two Boston women and asked "Which is in better nutritional status—Mrs. A or Mrs. B?" we often feel at a loss for an answer. When, a day or so later, we are asked to answer the same question with regard to Baby A and Baby B, we feel very frustrated indeed.

No doubt, if we were comparing the

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October '9, 1947.

† Studies referred to were supported in part by a grant from the Nutrition Foundation, New York City.

status of a small group of our patients with a group in China, or even in Birmingham, Ala., we could make a better showing for ourselves. But the difficulty is to rate *individuals* living in a region of relatively good nutritional circumstances. Perhaps a published example from a sound American study¹ in another northern state will show how this trouble arises.

Charts from Bethell's investigation of the relationship between the iron intake of Michigan women and the development of anemia during their pregnancies, showed that almost none of the women receiving the recommended daily intake of 15 mg. of iron became anemic. Of those with intakes below 8 mg., about 35 per cent did so. The chart thus clearly shows that iron intake is correlated with microcytic anemia. Yet these data indicate equally clearly that the clinician and laboratory worker could hope to appraise the past intake of iron correctly in only one out of every 3 pregnant women whose diets had contained one-half or less of the recommended daily allowance of an important nutritional item. Fully recognizing the risks of over-simplification, let us consider what might be expected of the infants produced by women on iron deficient diets. The classic work of Strauss² demonstrated that babies produced by mothers on such diets became significantly anemic at 6 months of age. He also showed that shortly after birth these infants of iron-deficient women had blood findings indistinguishable from those of infants born to women with good iron intakes.

After this rather querulous introduction to a very real dilemma, we may now examine the tools available for appraisal of nutritional status at whatever phase of life. These are (1) the *nutritional history*, (2) the general and specific symptoms and signs discoverable by *medical history* and *physical examination*, and (3) the results of *laboratory*

measurements. The first, of course, applies directly to the mothers and only indirectly to the new-born infants. Physical and laboratory examinations can, of course, be performed on both subjects.

1. Theoretically, the *nutrition history* has better potentialities than either of the other two. Obviously a laboratory scientist who knows *exactly* what an adult experimental rat (with normal absorptive powers) has eaten since birth should be able to compare that rat nutritionally with other rats of known intake. He could make a more accurate comparison by the nutritional history than by weighing the rat, feeling its hair, or measuring anything he might get from its blood or excreta. (If this hypothesis is not true it means that physical or laboratory findings are conceived to be more reliable than actual food intake. Probably no one would go that far—or would he?) To return to the matter in hand, we do not for a moment believe that the best nutritionist can get data as accurate as the record of a laboratory animal from a history of the most intelligent and coöperative mother. The point is, nevertheless, that the nutrition history *as a method* contains an element of direct relationship to the subject's nutritional state which is lacking in the other two methods. Otherwise the rather pernicious term "subclinical nutritional deficiency" would not be so often used.

If the inaccurate histories of vague informants are rejected as ruthlessly as would be laboratory measurements made with dirty glassware, if one includes an accurate record of the diet previous to pregnancy, and is careful to consider vomiting and other disturbances of absorption, the nutrition history offers an appraisal of unique value. We should especially like to stress the importance of diet before pregnancy in such a history, because of our Dutch experience. This indicated that mothers presumably

receiving an adequate diet previous to an acute period of nutritional deficiency show effects quite different from those appearing in pregnant women whose diets have been chronically inadequate.³

2. *Medical history and physical examination* as means of assessing nutritional status have disturbed us a good deal. It is somewhat revealing that at one point in our past efforts an obstetrician associated with our group said that he did not think he could rate mothers nutritionally, but he thought he could rate their babies, and at least one of our pediatricians thereupon mused that *he* was having a hard time rating the babies, but he would be glad to try rating the mothers. This simply illustrates the commonplace that the more closely one studies living organisms, the more cautious he becomes about quick judgments as to their individual superiority, inferiority, or, indeed, normality. Vilter, Morgan, and Spies⁴ have recently published an interesting description of the deficiency syndromes appearing during pregnancy. Although the frequency of individual symptoms was not tabulated, the authors indicated that such signs are brought into clinical prominence by pregnancy to a degree beyond their frequency in non-pregnant women. This is certainly what one would predict. Yet we have not found skin, eye, neurological, or other signs nearly so commonly in our pregnant subjects as logic and the literature would lead us to expect. For example, 11 cases of polyneuritis have been diagnosed in more than 45,000 pregnancies over the last 20 years at the Boston Lying-in Hospital. Indeed, we are so troubled by this state of affairs that arrangements are now under way to send a member of our group to study in another region of the country at a nutrition clinic where these physical signs are reported much more frequently than we are able to discover them.

So far as examining the *infant* for physical evidence of nutritional ade-

quacy, the problem is even more challenging. There are plenty of evidences that human fetal growth results in a fairly standardized product—at least in terms of nutrition and its components circulating in the blood stream. This is shown by the extraordinary rarity, in neonatal life, of the common nutritional deficiencies of infancy—rickets, scurvy, and anemia. It may be that only by following infants over 6 to 12 months after birth can one really appraise what is hidden in them when born. Such a method, of course, would have to be safeguarded by appraisal of nutritional and environmental factors added to the baseline established at birth. It would not be easy.

Variations in length and weight at birth, so easily correlated with maternal nutrition in animal studies, are not sufficiently specific to be relied upon in appraising the nutrition of the new-born infant—or, at least, in relating his nutritional status as an individual to that of his mother as an individual. This appeared in our study of pregnancy in undernourished women in Holland. The distribution curves indicated that birth weight and length fell as starvation continued, but many individual women who had lost weight during pregnancy gave birth to infants above the length and weight averages of those born to well nourished women in times of peace.

This failure of fetal weight gain to be a consistent reflection of maternal nutritional status is also a drawback to the use of special methods such as x-ray appraisals of osseous development and of measurements of tissue breadths as more delicate means of estimating the nutritional status of infants. Indeed, all we feel able to say at the moment is that the infant's size, as well as the amount and character of his measurable tissues, are in some measure, but by no means wholly, dependent upon maternal nutritional intake.

3. It was, therefore, our hope to find in

laboratory measurements the means of accurate nutritional appraisal. This seemed likely to reveal some useful mathematical data by which mother could be compared with mother, infant with infant, and (most desirable of all) infant nutritionally correlated with mother. As with Bethell's study of iron intake described above, we soon learned that correlations between maternal protein and vitamin intakes and the blood levels of these items are loose. Actually, correlation *can* be demonstrated for most items if sufficiently large groups are used. For ascorbic acid, the correlation between maternal intake, maternal blood level, and neonatal blood levels demonstrated sometime ago by Teel and Burke² is one of the closer ones. For vitamin A, there would appear to be almost no correlation at all. For other items, particularly riboflavin, we attempted to get our own information.

Warned by Dr. Lowry and others not to draw conclusions about riboflavin from blood levels, we worked a long time at trying to evaluate assays of this substance in the urine of new-borns. Unhappily, these subjects are notoriously uncoöperative in the matter of timed urine specimens. Therefore, we put in a good many hours appraising creatinine excretion as a guide to adequacy of urine collection. It would have been most satisfactory if new-born infants exhibited that constancy of creatinine excretion characteristic of adults. Unfortunately, as Dr. Stearns has indeed already shown, creatinine is not excreted in constant daily quantities by new-born infants. This exemplifies another difficulty of laboratory measurements in the neonatal period, a time when performance of the kidney obeys somewhat different laws from those which govern its performance during adult life.

For these reasons, and because the really important matter is not how much of a nutrient is circulating or being ex-

creted, we have recently been measuring the various nutritional items stored in the liver. This, of course, involves confining our present efforts to miscarriages, stillbirths, and neonatal deaths. It does not mean at all that we have given up as insoluble the problem of laboratory appraisal of nutrition in the living infant. Information as to storage, secured from a small, carefully studied series, does seem to offer a foundation of fact upon which we hope to proceed more wisely with the blood sample techniques applicable to clinical material.

In summary, our experience indicates that no satisfactory methods are yet available for the *exact* appraisal of nutritional status in individual pregnant or puerperal women and in individual new-born infants. Relations which may have statistical significance in interpreting the diet of pregnant women in groups are not always applicable to the interpretation of the state of nutrition of the individual. This is particularly true of subjects under relatively good nutritional circumstances. In more obvious degrees of starvation and malnutrition, the appraisal becomes easier. Even in those ranges the infants will differ largely in distribution curves constructed from measurements made upon groups. No single measurement gives promise of being especially useful; nutrition histories, physical examinations, and laboratory tests must be combined.

In view of the more than medical significance of the problem, the absence of simple methods for appraising nutritional status of mothers and infants is an important challenge to the ingenuity of workers in obstetrics, pediatrics, and nutrition.

United Nations Appeal for Children

The Association's 75th Annual Meeting in October adopted a resolution of approval of "the program of the International Children's Emergency Fund and urges that it receive full and immediate support of the government and people of the United States."

The channels through which immediate and material support can be given to the program have now been announced. The United Nations Appeal for Children for the sinews of the war against starvation is being made through a federation of major voluntary foreign relief agencies designated by President Truman to handle American participation in the world-wide appeal for children. This organization, the American Overseas Aid and United Nations Appeal for Children, in February began a \$60,000,000 campaign to provide funds for the International Children's Emergency Fund and 24 private overseas relief agencies.

Up to now the Children's Fund has been supported largely by governments, the United States having made an ini-

tial contribution of \$15,000,000 with another \$25,000,000 to be made available on a matching formula. Pledges from 14 governments and UNRRA totaled \$40,000,000 in mid-January.

In January, the Emergency Fund was providing a daily supplementary meal to nearly four million children and pregnant and nursing mothers in 12 European countries. This feeding is done through infants' and children's centers, schools, orphanages, and maternity centers.

Maurice Pate of the United States is Executive Director of the Fund, Dr. Ludwik Rajchman of Poland is Chairman of its Executive Board, and Martha M. Eliot, M.D., is its Chief Medical Consultant.

A Schick Survey of 18,000 Naval Recruits*

F. S. CHEEVER, M.D.

*Department of Bacteriology and Immunology,
Harvard Medical School, Boston, Mass.*

THIS paper is a preliminary report of the results of a Schick survey carried out among naval recruits in the period October, 1941—January, 1942, under the direction of Captain LeRoy D. Fothergill, Medical Corps, U. S. Naval Reserve. The purpose of the survey was twofold—first: to determine the percentage of recruits susceptible to diphtheria, and second: to determine what proportion of these susceptibles could safely be immunized with diphtheria toxoid. The rapid mobilization of men from all parts of the country for military training and service during the latter half of 1941 had created conditions favorable to the spread of many communicable diseases—and particularly those whose etiological agents gain entrance to the body via the respiratory tract. The 1940–1941 outbreak of diphtheria in Halifax had drawn attention to the dangers of a situation in which a virulent

strain of the diphtheria bacillus was introduced into a relatively susceptible population living under conditions of marked overcrowding. Since the status of an individual's immunity against diphtheria could be determined easily, and since effective means of artificial immunization were available, it was felt that such a survey would yield valuable information as to the possibilities of an outbreak of this disease, and as to the feasibility of a program of active immunization with diphtheria toxoid.

The recruits examined, over 18,000 in number, were drawn from all parts of the country. They had been newly inducted into the Naval Service, many of them within a matter of days, all of them within a few weeks. They were divided among the four U. S. Naval Training Stations in operation at that time, as shown in Table 1. The great majority of the recruits tested were

injecting intradermally into one forearm 0.1 ml. of a standard diphtheria toxin so diluted that 0.1 ml. contained 1/50 m.l.d. The Moloney test was performed simultaneously by injecting 0.1 ml. of a 1:100 dilution of diphtheria toxoid into the other forearm by the intradermal route. The tests were read and the measurements of any positive reactions recorded at the end of 48 hours, and again at the end of 120 hours. The interpretation of the measurements of the individual tests were all carried out by one person (Captain Fothergill). Pertinent data concerning each recruit were collected at the time the test was performed. These included name, age, place of birth, place of residence before and after the age of 10 years, any history of an attack of diphtheria in the individual or in members of his immediate family, and finally any history of active or passive immunization against diphtheria.

The results of the Schick tests are summarized in the last 2 columns of Table 1. The incidence of Schick-positive reactors for the group as a whole

was 34.2 per cent, i.e., according to the Schick test approximately 1 recruit out of 3 was susceptible to diphtheria. The results of the Moloney tests are given in Table 3. The incidence of positive Moloney reactions among susceptible recruits (i.e., those giving Schick-positive reactions) was 24.4 per cent. Thus, approximately 1 susceptible recruit out of 4 would have reacted unfavorably to injections of toxoid had it been necessary to institute a program of immunization with this agent. As was expected, the incidence of positive Moloney reactions was significantly higher in recruits giving negative Schick tests.

The marked variation between the incidence of Schick-positive reactions in the four subgroups (i.e., 16.6 per cent at Norfolk as compared to 47.5 at Great Lakes) suggested further breakdowns in an effort to determine what factors could be correlated with susceptibility to diphtheria. Recruits were divided according to the geographical area (New England, Mid-Atlantic, South Atlantic, East South Central, West South Central, Mountain, and Pacific) in which they were born, in which they resided until the age of 10, and in which they lived after the age of 10. The figures for these three groups parallel each other reasonably closely.

The incidence of Schick-positive reactions was significantly higher in the northern half of the country no matter what classification (birthplace, residence to age 10, residence after age 10) was used. The reasons for this are not clear. The relatively greater amount of clinical

TABLE 3

(and presumably subclinical) diphtheria in the South at present may be the important factor in the lower incidence of individuals susceptible to the disease, or again more vigorous campaigns for active immunization against diphtheria may be the cause. These and other possible factors require further analysis before an accurate appraisal of their relative importance may be made.

The incidence of Schick-positive reactions classified according to the age of the individual recruit is shown in Table 4. Contrary to expectations the percent-

| Total | 18,499 | 6,311 | 34.1 |

age of recruits susceptible to diphtheria increased rather than decreased with age, and there was no evidence that any gradual immunization of the population presumably due to clinical or subclinical attacks of the disease occurred between the ages of 17 and 26. It is planned to analyze these figures further by comparing the age trends in different geographical sections of the country.

An attempt was made to evaluate the effect of a history of artificial immunization upon the incidence of positive Schick reactions. Recruits giving such a history were classified according to the interval since immunization, and the incidence of positive reactions compared. The results are given in Table 5. Similar studies were done on the groups giving a history of clinical diphtheria in the

able inaccuracy of an unknown percentage of the histories, the figures as obtained did not show a marked correlation between the incidence of positive Schick reactions and the interval since

the occurrence of any of these three events.

It is obvious that further statistical analysis is necessary before the significance of these figures can be assessed. Other factors which may be correlated with the incidence of Schick-positive reactions are being investigated. It is planned to supplement this brief preliminary report with a more detailed and complete analysis of all these factors.

SUMMARY

1. A Schick survey of 18,499 naval recruits revealed that 6,311, or 34.2 per cent, gave positive Schick reactions.

2. Of these 6,311 recruits presumably susceptible to diphtheria, 1,538, or 24.4 per cent, showed positive Moloney reactions when tested for sensitivity to diphtheria toxoid.

3. The incidence of susceptible recruits was significantly higher in men coming from the northern part of the United States as opposed to those coming from the southern part.

4. The percentage of recruits giving positive Schick reactions increased with age.

NOTE: This survey was carried out by the following medical officers: Capt. R. W. Babione, MC, USN; Cdr. F. A. Butler, MC, USN; Cdr. F. S. Cheever, MC, USNR; Cdr. J. N. DeLamater, MC, USN; Cdr. R. A. Mount, MC, USN; Cdr. O. F. Munch, MC, USNR; Lt Cdr. L. R. Schoolman, MC, USNR.

Dental Health Education Services of the American Dental Association*

GLENN A. G. WALTER

Dental Health Education Consultant, American Dental Association, Chicago, Ill.

THE American Dental Association has the responsibility of offering leadership and guidance in a dental health education program at a national level. Its dental health education services are planned as part of an integrated general health program, and emphasis on the need of accepting the responsibility for dental care is directed toward the individual, family, and community in that order.

The following objectives have been adopted by the American Dental Association for the national dental health program:

1. Help every American to appreciate the importance of a healthy mouth.
2. Help every American to appreciate the relationship of dental health to general health and appearance.
3. Encourage the observance of dental health practices, including personal care, professional care, proper diet, and oral habits.
4. Enlist the aid of all groups and agencies interested in the promotion of health.
5. Correlate dental health activities with all generalized health programs.
6. Stimulate the development of resources for making dental care available to all children and youth.
7. Stimulate all dentists to perform adequate dental health services for children.

Although the overall program for dental health education is directed toward the individual's responsibility and the facilities available in his particular com-

munity, the American Dental Association has established certain principles to govern the operation of this national dental health program.

These four principles act as a guide and a control from the national level:

1. *Research*—Adequate provision should be made for research which may lead to the prevention or control of dental diseases.
2. *Dental Health Education*—Dental health education should be included in all basic educational and treatment programs for children and adults.
3. *Dental Care*—
 - a. Dental care should be available regardless of income or geographic location.
 - b. Programs developed for dental care should be based on the prevention and control of dental diseases. All available resources should first be used to provide adequate dental treatment for children and to eliminate pain and infection for adults.
 - c. Dental Health is the responsibility of the individual, the family, and the community in that order. When this responsibility is not assumed by the community, it should be assumed by the state and then by the federal government. The community in all cases shall determine its methods for providing services.
4. *Participation in Program Planning*—In all conferences that may lead to the formation of a plan for dental research, dental health education and dental care, there should be participation by authorized representatives of the American Dental Association.

The first responsibility of the American Dental Association in a national dental health program is to keep the members of the dental profession informed of the results of all scientific dental research, and the basic dental health concepts that are developed. An

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

explanation of all phases of the dental health education program is presented to the professional membership, and they are encouraged to participate in the dental health education activities as part of an integrated general health program in their community.

The dental health planning workshops in the state and local dental societies have been organized to study the dental health problems in a particular area, and should be first in any discussion of what is being done by the American Dental Association in dental health education. These workshops are organized by the state and local dental societies with the assistance of the Council on Dental Health of the Association, and offer a means of coördinating the work of the local, state, and national councils on dental health. These workshops have been held in Ohio, New York, Louisiana, New Jersey, Georgia, Connecticut, and Minnesota. Illinois, South Dakota and Oregon plan to hold workshops within the near future.

The workshop offers an administrative framework for coördinating functions, but the Councils on Dental Health at the local and state level offer guidance and leadership in dental health education to the general health program of the community in the same manner that the Council on Dental Health of the American Dental Association offers guidance and leadership in dental health education to the national health program.

It is impossible for the present dental personnel to meet the present dental disease problem, and prevention through education is the only possible solution. The schools, established health and welfare agencies, allied professional societies, commercial companies, and service organizations have trained personnel who are usually qualified to present their particular type of service at the time and place most meaningful to the individual, and it seems important that

dental health facts should be made available to these qualified people in a manner that can be most efficiently integrated into the general health services. It is with this thought in mind that most of the dental health education literature and activities are being planned.

Consultation services are available to official and voluntary agencies in the formation of policies for a practical and effective integration of dental health programs. It is hoped that this will prevent a feeling of being "told what to do"; but will give an opportunity for the individual to learn good dental health habits that are consistent with his particular problem and environment. The same opportunity is offered to the community; in studies of their own local dental health problems, and needed available factual information prepared to be used by the personnel of their own health services. In other words, each community, and each agency in the community has the privilege and responsibility of solving its own dental health problems; but professional guidance and factual information are made available for that purpose.

The dental health education program of the American Dental Association consists of two general services:

1. Advisory and consultative assistance in dental health education is provided free of cost to all component and constituent dental societies, departments of health and education, professional and lay organizations, commercial agencies, and to authors and publishers of school textbooks and magazines. This consultant service makes it possible to interpret present dental health concepts which are factually correct and consistent with scientific research to a group of people who have facilities for reaching a large segment of the population without employing a new tool or additional personnel in any one specialized field.
2. The second service is the production and distribution of dental health education aids, which include printed materials, films, film strips, and slides; magazine and newspaper articles; radio scripts and transcriptions, and exhibit materials. These dental health edu-

cation aids are distributed directly to the public, but it is preferable to supply them to an agency that can give the necessary motivating preparation and follow-up services to make the materials most meaningful to the individual and the community. There will be a limit on the number of pieces of material that can be obtained from the American Dental Association, but this is the result of keeping dental health information factually accurate and consistent with dental research. A definite nomenclature is being established for use in dental health literature, which will be helpful in all teaching procedures.

It is important that teachers and the personnel of all official or voluntary agencies who are participating in the teaching of dental health education should have had not only the opportunity to learn the basic dental health facts, but have also experienced good personal dental care.

The need for dental health education materials to be used in teachers' training schools, nurses' training schools, social service training divisions, and in all schools of public health as well as the materials needed immediately for inservice preparation of classroom teachers, school administrators, nurses and physicians, and other specialized groups are recognized by the dental profession and will be met as quickly as possible.

You will notice when you review the dental health education materials that are available from the American Dental Association that there are 3 dental health rules employed in all of the information distributed to the general lay public:

1. Visit your dentist at least every 6 months or as often as he recommends.

2. Eat an adequate diet, restricting refined carbohydrates, especially sugars. Emphasis is being placed on the limitation of soft drinks, candies, and chewing gum.

3. Brush your teeth properly and thoroughly immediately after eating. Special attention is being given to pointing up the fact that the dentist is the person who should determine the best method of toothbrushing for the individual mouth and prescribe the correct type of toothbrush and dentifrice to be used.

It is essential that these basic principles of dental health be understood and be made meaningful to every individual if we hope even to begin to control the problem of dental diseases. This can be done only by everyone coordinating his information and efforts with all of the facilities that are available in each community. The layman is extremely busy, and cannot be expected to spend much time or effort on lengthy reports, but will use a few facts that are presented to him time and time again. The assimilation of these facts into a satisfying experience will finally result in a desirable dental health habit. It is extremely important that good personal dental health habits are formed early in life.

Unfortunately, dental caries, which is the most prevalent dental disease, is always more rampant during youth. This is an age period filled with many more interesting and exciting things to do than conscientiously to follow a daily dental health routine for which little or no personal recognition is given. Irregular dietary habits, and the desire for confections at this age all add to the total lack of dental health in our youth.

Again, I want to say that this type of teaching must be done by personnel who have an opportunity for frequent contact with the individual whose attitude toward dental health is being influenced. Dental disease is not dramatic, and does not in most instances necessitate hospitalization. Therefore, it lacks much of the emotional appeal that is being used to stimulate interest in other diseases in a national prevention program. Dental diseases are slow, insidious processes and require a day-to-day attack.

Although dental disease is the responsibility of the individual, it must be recognized as a community public health problem, and all of our combined efforts are constantly required to attain the highest potential level of dental health—through dental health education.

International Trends in Health Care

JOHN B. GRANT, M.D., F.A.P.H.A.

International Health Division, The Rockefeller Foundation

DEVELOPMENTS outside North America in health care during the past decade have been almost revolutionary. Activity centers in European countries and in the British Commonwealth. In carrying out under the auspices of the International Health Division of The Rockefeller Foundation a preliminary survey of work and literature in the field of health care, twelve countries were visited. These countries were Australia, Canada, Denmark, England, Finland, France, The Netherlands, New Zealand, Norway, Sweden, Switzerland, and the United States. In what follows an attempt will be made to reproduce the main impressions received during this travel and to give at the end a list of chief items in the literature.

In spite of the remarkable amount of work already done, there is not yet available a universally accepted definition of health care or any clear agreement on its scope and contents. At the outset, however, the International Health Division of The Rockefeller Foundation in arranging for the above mentioned survey was prepared to accept the following assumptions:

Health of mind and body is a basic human need. A healthful community is a basic social need. *Social Medicine*, which has as its aim the meeting of these needs, is committed to a program of curative and preventive measures for the protection of the individual and the community against whatever interferes with full development and maintenance of both mental and physical capacity. It is also prepared to advance beyond these measures to the promotion of positive health through application of sociological techniques and methods.

Social Medicine, Medical Care, or Health

Care are so interchangeable as to be almost synonymous. Preference, following South African usage, should perhaps be given to the term *health care*.

Adequate Medical Care makes available to every individual in the community, without discrimination, all facilities of medical science necessary to achieve and maintain optimum health of mind and body.

The General Medical Council of Great Britain specifies more particularly that adequate social medicine aims "to seek and to promote measures, other than those usually employed in the practice of remedial medicine for the protection of the individual and of the community against such forces as interfere with the full development and maintenance of man's mental and physical capacity." Thus, medical care extends clinical medicine beyond clinical diagnosis to social pathology and therapy, thereby making it the task of medicine to assure a mentally and physically healthful community.

By any interpretation it is clear that the "full development and maintenance of mental and physical capacity" depends not only on adequate medical services but also on minimum standards of nutrition, housing, recreation, education, and social security. Acknowledgment of the importance of these non-medical factors comes out clearly in the principles of policy adopted today by most organized medical professions, such as the first and last of the ten principles of the American Medical Association, stated in June, 1945, and restated in February, 1946, which are concerned with providing necessary non-medical factors by community efforts and government aid, if it is not possible

to gain them by individual effort.¹ The South Africans have adopted the term health care in preference to medical care to emphasize the non-medical promotive and rehabilitative, as well as the medical preventive and remedial, essentials needed to arrive at full mental and physical capacity.

The provision of *medical* services depends upon three prerequisites. These are: removal of economic barriers; sufficient personnel and facilities, properly distributed; and, finally, a high degree of technical excellence in both medical personnel and equipment. Economic barriers to health care can be removed only through organized voluntary or compulsory measures. Medical personnel with adequate training must be available in sufficient numbers to deal with significant social and environmental conditions as well as clinical pathological symptoms. However, neither removal of economic barriers nor provision of adequate personnel suffices, unless there is a proper geographical distribution of both personnel and technological tools.

In deciding upon the scope of health care, two final generalizations should be taken into account. Effective measures for health promotion, disease prevention, and rehabilitation require government action and cannot be attained through voluntary initiative. This is possibly true even of curative medicine. Even in the United States some legislation is already on the statute books with respect to each of these four services, and Senator Taft's health insurance bill, limited as it is, would extend facilities for care beyond the public assistance group. The second generalization is that legislation should not be of a negative nature based on political grounds, generally due to considerations of labor, but of a positive nature based upon social-economic necessity to promote the quality of population.

The first stage of social welfare, de-

veloped a century and a half ago in England, consisted of paternalistic legislation largely to relieve outstanding ills. It was based solely upon humanitarian and philanthropic motives. All countries have passed this stage. The second period, developed some sixty years ago in Germany, dealt with social insurance. Such insurance was motivated by political considerations. The purpose was to provide security to labor by pooling risks through unemployment insurance. Most countries, including the United States, are in this second stage. The third stage is based squarely upon a population policy which aims to improve the quality of human capital by legislation directed toward removing the causes of social ills. Swedish, Danish, French, and, to a growing extent, Finnish legislation is now based upon recommendations of commissions considering the improvement of population. The report of the English Population Commission will appear in 1948.

It should be borne in mind that the component parts of legislation always vary with the economic philosophy of the political party enacting the legislation. The English Health Services Act of 1946 was inevitable with either a Labour or Conservative government in power, but the Conservatives would not have nationalized the hospitals. A health insurance act seems inevitable in the United States, but the Wagner Bill differs in shape from the Taft Bill.

The foregoing constituted the base line upon which the survey was made and by which trends were interpreted. The survey was concerned primarily with strictly medical trends, but note was also taken of essential developments in non-medical measures required for the maintenance of mental and physical capacity. The latter will first be briefly reviewed.

NON-MEDICAL FACTORS

1. *General Security*²—Strictly non-

medical social welfare legislation to provide security has, generally speaking, been enacted earlier and in more comprehensive form than legislation based upon medical or population considerations. Previous to 1937 Danish legislation was the most comprehensive, but Denmark has now been passed by New Zealand, Britain, and France, and shortly will be by Sweden. Thus, the English 1946 National Insurance Act³ provides nation-wide coverage for old age and invalidity, widows and orphans, unemployment, workmen's compensation, and funerals, as well as cash benefits for illness. All of these countries now provide one or more of the foregoing to restricted population groups. Countries having nation-wide coverage, apart from medical services, legislate specifically to promote health. Such legislation provides family allowances, disability training, and various help for married women, including maternity benefits. Family allowances, except for the United States, are now universal. In England it is a matter of national interest to help parents to maintain their children. A substantial part of the benefits is given in kind through school meals and milk services, which cost the nation 60 million pounds a year. In addition, there are 69 million pounds for cash allowances. Individuals requiring refresher training as a part of disability rehabilitation are given an allowance in excess of unemployment benefit. Women receive a maternity grant of 4 pounds, and if gainfully employed, a maternity allowance of 36 shillings a week for 13 weeks. Women not eligible for the latter allowance receive an attendance allowance of a pound a week for 4 weeks to provide domestic help, in addition to the maternity grant. In France there is, in addition, an allowance during pregnancy. Publicly provided home-aid services constitute an important international post-war development.⁴

The amount of social security costs paid from insurance premiums varies in different countries from 40 to 70 per cent, the balance being met by funds derived from the general exchequer. The English social insurance costs including health for 1948 will require at least 10 per cent of the national income, while the South African estimate for 1955 is 15 per cent. The United States federal expenditures in 1946 on social welfare constituted 1.3 per cent of the national income. It is of interest to know that in addition to the general income tax, both New Zealand and Australia levy a special welfare tax of 1/6 on the pound.

2. *Housing*⁵—Measures more immediately promoting health deal with housing, nutrition, recreation, and education. There are two types of government housing policies, an older one based on rental returns and a newer one on population needs. Outside of North America, Holland is the only country where rental returns still predominantly determine government policy. The same policy is advocated in the Taft-Ellender-Wagner Bill. Sweden has evolved the clearest example of a policy determined solely on population needs with no reference to rental returns. This policy acknowledges that the majority of families cannot pay rentals high enough to yield a profit on the housing they require. Consequently, the Swedish Government, in addition to granting third mortgage loans up to 95 per cent of the value of the property, guarantees the interest on the first and second mortgage loans, and also supplements the third loan by tax subsidies. The government without a means test also underwrites from 30 to 40 per cent of the rent. The exact amount depends on the number of children. Housing policy in the other countries reveals a similar trend. Finland, Norway, and Denmark, although providing for rent allowances determined by the number of children, have certain

variations. For example, Denmark has an upper income bracket, the allowance is paid only after the third child, and the family must live in a state-designated house. In New Zealand less than 1 per cent of houses are built on a rent return basis, and government subsidies keep the maximum rental at 25 shillings a week. Even this is more than paid for by the family allowance of 10 shillings per child per week if there are three children in the family. There is increasing international acknowledgment that rentals should not exceed 20 per cent of the wage of the laboring group.

Every country now has a national housing agency, and a number have town planning agencies. Planning is much occupied with neighborhood units of 10,000 population, some of which provide for health centers. Research is an important feature in England, Holland, and Denmark. Housing has been related to health in international literature, but due to the initiative of the American Public Health Association,⁶ the United States is the only country where such health standards have been specifically formulated.

3. *Nutrition*⁷—All European countries except Holland are establishing food policies resembling those already operating in Great Britain and Sweden. Among the items included in these policies are free or subsidized protective foods to specific population groups, enrichment of certain foods, free school lunches, price control backed by subsidies, and increased production of essential foods, particularly milk. None of the four nations of the British Commonwealth has, as yet, adopted an overall nutrition policy. South Africa, which has done so for a small percentage of its population, is an exception. However, all of the twelve countries to a greater or lesser extent provide school lunches.

4. *Recreation*—The need for mental,

social, and physical recreation, acknowledged by the American Medical Association in its tenth principle, is increasingly provided for through community centers. The underlying principles illustrated by the Peckham Center⁸ in England are that to enjoy physical and mental health the family unit must have normal social and biological outlets. These are available in rural agricultural communities, but not in industrial centers. The Peckham neighborhood unit, with its freedom of social activities and adequate admixture of families from different walks of life, permits spontaneous social-biological development, thus correcting maladjustments which make positive health unobtainable. Community centers are developing more rapidly in England than elsewhere because they became mandatory under the Education Act of 1944. South Africa has ambitious plans. The National War Memorial Health Foundation established by the veterans of the recent war is now soliciting 5 million pounds for a war memorial to take the form of 400 community centers similar to the Peckham experiment, to be erected beside each of 400 health centers in process of construction by the Ministry of Health.

5. *Education*⁹—Conventional health education of either the "propaganda" or the standard school instruction type is found to a greater or lesser extent in each country. The only effective departure from convention has been gradual introduction of the "workshop" technique in the United States and Canada, whereby representative lay leaders of the community under the direction of a trained individual discuss prepared material concerning medical care. During such a seminar, lasting one or more days, participants reach their own conclusions on what steps must be taken to meet community educational needs. These techniques have been most successful in Manitoba and in some of the

western states. The Farm Foundation and the Interbureau Committee of the U. S. Department of Agriculture, through its Farm Security Administration, are developing work of this pattern in various parts of the United States. The program is to have each agricultural college appoint a qualified worker who endeavors to have the surrounding area take the initiative in establishing prepayment plans for medical care, obtain personnel and facilities, and establish and strengthen local public health units. Presumably health departments should extend the scope of their educational activities to cover the field of medical care.

The most significant of the foregoing "non-medical" trends is to make population policy^{10, 7} a determining factor in welfare legislation. Such policies are still largely empirical and will not become scientific until disciplines are developed in social physiology, pathology, and therapy, directed specifically toward the development of the mental and physical capacity of man in relation to his environment and his community. This scientific development is a responsibility which universities are only just now beginning to undertake. University leadership could be achieved through an extension of the existing medical and other university disciplines, with a sound biostatistical approach, into such social sciences as anthropology.

MEDICAL FACTORS

It has been stated that the adequate provision of medical services for prevention of disease, cure of illness, and rehabilitation of disability requires removal of any economic barrier; adequate and geographical distribution of medical facilities and personnel; and a high technical excellence of the personnel and their tools. Recent legislative trends and thinking in these three essentials during the past decade display an almost revolutionary trend.

The overall international legislative picture is summarized in "Health Insurance, A Report of the Canadian Parliamentary Committee on Health Insurance."¹¹ A recent summary of North-western Europe is given in two U. S. Public Health Reports.¹²

1. *Economic Barriers*—Denmark is the only country which for a majority of its population over a decade ago provided medical care, largely on a "voluntary" basis.¹³ The other Scandinavian countries, while giving practically nation-wide hospitalization, were providing medical services to only a part of their populations, chiefly through mutual aid societies. The situation is changing very rapidly. New Zealand, beginning in 1938, enacted legislation which now provides comprehensive care, including free hospitalization, on a nation-wide basis for all services except specialists.¹⁴ The Germans during their occupation of Holland put through forcibly compulsory insurance for a comprehensive service based on a means test. France, as of January, 1947, inaugurated universal coverage as comprehensive as that of any other country.¹⁵ A similar Health Services Act in the United Kingdom is due to be inaugurated July, 1948.¹⁶ A similar Swedish Act begins operation in 1950. The South Africans and Australians, since the war, have provided nation-wide, tax-supported hospitalization as a first step in a planned, and comprehensive nation-wide coverage. The Finns also, since the war, are proceeding to provide this as rapidly as their special economic circumstances will allow. Norwegian legislation is in the drafting stage. Canada published in 1945 its White Paper¹¹ for comprehensive national health insurance, approved by its Medical Association. Failure of implementation has been due chiefly to broad non-medical economic factors relating to the division of fiscal powers between the Dominion and the Provinces. In the meantime.

Saskatchewan has inaugurated compulsory hospital insurance. Here in the United States there are the recurring and pending Wagner and Taft Bills, while the Hospital Survey and Construction Act¹⁷ is already law.

The only two countries in which insurance on a voluntary basis continues to receive consideration are Denmark and the United States. Insurance in Denmark is in reality only partially voluntary, because hospitalization for the 100 per cent population covered is entirely tax-supported, and medical services for the 80 per cent covered through the friendly societies are supported more than 60 per cent by taxes. It is stated that in the United States as of July 1, 1947, there were twenty-seven million enrolled under Blue Cross hospitalization plans, and six million enrolled under fifty-six medical society-sponsored plans. Membership in the latter is generally restricted by income level, and coverage is limited. It is estimated that some nine million persons carry commercial indemnity insurance for more or less limited coverage. The details of the present trend for medical care in this country are extensively reviewed in *Medicine in the Changing Order*¹⁸ and *Blue Cross and Medical Service Plans*.¹⁹

It is now anticipated that Britain's comprehensive medical care coverage will cost 200 million pounds for 1948-1949, or approximately \$20 per capita. The premiums received from insurance will meet less than one-third of the cost.

Britain's national income and total government expenditures for the year ending March 31, 1946, were approximately 5,500 million pounds each. Expenditures for the same period for social security and welfare, exclusive of education, were a little over 500 million pounds. Because of the large military expenditures included in this period in the total government expenditures, the proportion given to social security and welfare is perhaps not that of a typical

year. For a population of 1.7 million, the approximate 1944 figures for New Zealand were, for national income 300 million pounds; government expenditures, 100 million pounds; social security, including medical, 43 million pounds; and health coverage, 7 million pounds—the latter being in the range of \$13 per capita, with the New Zealand pound reckoned at \$3.25.

England, Denmark (mainly), and the Netherlands provide a capitation basis for paying general practitioners. Specialists are paid either through part-time salary or, more commonly, on a fee-for-service basis. In England they will be paid entirely on a part- or full-time salary basis. France and Sweden require that the insured person bear a part of the cost of the medicine and services provided by the general practitioner.

Three major defects in the planning of legislation for medical services seem common to the countries visited. The most serious is the complete failure, except in regard to physicians in Australia, to consider the categories and number of personnel required and the training needed to implement the organization envisioned by legislation. Second, except in South Africa, planning and legislation are for sickness rather than health insurance. Third, invariably there is inadequate provision for the three chief lags in medical care today: chronic, mental, and rehabilitative services. In addition, there are two minor defects. Planning in most countries has gone ahead in water-tight compartments without adequate reference to what is developing in other countries. Generally speaking, such observers as were sent abroad saw only established activities and overlooked the embryonic developments, which in ten years will establish the unmistakable pattern of tomorrow. Also there is almost complete disregard of the need for auxiliary medical personnel. The

United States, and, to a lesser extent, Canada are the only countries where the training of auxiliary medical personnel in all categories, except practical nursing, has become standardized, with the level of training controlled by a national organization. Similarly, these two countries are the only ones where hospital administration with regard to standard records, etc., has reached a level at all satisfactory.

One was struck by the preoccupation of national health administrators with medical services and legislation, to the exclusion of general health problems. This is true in spite of the backwardness of a number of countries in non-personal general services, environmental health and epidemiology, including laboratory diagnostic services. There is not enough recognition in these countries that a successful medical care program can be reared only on the foundation of an adequate public health program.

2. *Geographical Distribution of Facilities and Personnel*—The chief aspects to be considered are regionalization of institutions, bed requirements, numbers and function of health centers. Adequate regional distribution of institutional facilities is a need which has been increasingly accepted since the publication of "Future Provision of Medical and Allied Services"²⁰ by the British Ministry of Health in 1920. This report is the basis for "Health Services Areas"²¹ and other national planning proposals,²² including the official recommendations of a number of medical associations. Regionalization is enacted in the British Health Services Act (1946)¹⁶ and constitutes the chief basis of the recent report, *Hospital Care in the United States*.²³ France also has a scheme now being implemented for the national regionalization of hospitals and health centers very similar to the English plan.²⁴ The Scandinavian countries, beginning with Denmark (1925), have zoned hospitals to give each designated

region smaller "mixed" hospitals as well as a "central" hospital possessing medical and surgical departments with diagnostic facilities. But there has been no organization for the coordination described in the American experiments.

The overall pattern in different countries is similar. Efficient regionalization provides for institutions at three to four levels, the health centers at the periphery stemming back through community and district hospitals to a coordinated base, which preferably should be a teaching institution. There should be a two-way flow between base and periphery, which assures routine services at each level for diagnosis, consultations, and continuation education. However, no country has as yet an example of such fully coordinated regionalization. If one were available, it would constitute a most potent factor in bringing about more adequate medical care.

Three significant experiments toward this end are now in process in the United States under the auspices of the Bingham Associates,^{25, 26} Boston; the Council of Rochester Regional Hospitals,²⁷ Rochester, N. Y.; and the Michigan Community Health Program.²⁸ Foremost trends and experiments are summarized in "The Health Department and Medical Care — Certain Trends."²⁹ The most discussed physical aspects of regionalization are the number of beds and health centers required in terms of population units.

The overall pattern emerging from these three experiments has remarkable uniformity: A regional group of hospitals expresses an interest in associating with a teaching base hospital. The local diagnostic facilities are surveyed and strengthened both as to equipment and personnel. The technicians in the smaller hospitals are supervised by full-time specialists at the designated larger hospital. Qualifications for medical staff membership are laid down. The hospital service is departmentalized at

least into medicine and surgery, and assistant residents from the base inaugurate teaching ward rounds. A teaching resident is made available for one or more hospitals. As a result, central pathological conferences are instituted at routine periods, supplemented by special teaching clinics, which may or may not be conducted by specialists from the teaching base. Further steps are the inauguration of continuation education for the local medical practitioners and the institution of graduate training for specialists. The affiliated hospital meets the requirements of the board of the specialty in which training is to be given. The assistant resident proceeding to the teaching base in the second year for training in the basic sciences is replaced by an assistant resident from the teaching center. The candidate returns to the parent hospital for his third or additional resident years. As an additional feature the teaching hospital provides consultations in the regional hospitals and also "refresher" courses at the base, extended gradually to all categories of personnel besides physicians. The scheme, when complete, establishes satisfactory diagnostic services and continuation and graduate education.

Hospitals—Discussion of the number of beds required has resulted in a special bibliography. In what follows some of the more important English references are noted. Most of the figures are derived empirically. The two most careful overall studies of requirements are those of the Hospital Council of Greater New York³⁰ and of the Commission on Hospital Care.²³ The latter bases requirements on a bed-death ratio. This ratio varies from community to community, but offers a better guide for planning than empirical results or experiences based on actual hospital days as used by the Committee on the Costs of Medical Care.³¹ The total of 16.1 beds per 1,000 population (Table 1) taken from the Report of the Hospital Council of

TABLE 1

| | <i>Beds per 1,000 Population</i> |
|----------------------------------|--------------------------------------|
| General Care | |
| Residents | 4.0 |
| Non-residents | 0.2 |
| Convalescent Care | 1.0 |
| Long-term Illnesses | 2.0 |
| Acute Communicable Diseases..... | 0.1 |
| Tuberculosis | 0.8+ |
| Psychiatric Patients | 8.0 |
| | <hr/> 16.1+ |

Greater New York is of particular interest in view of the goal of 15 beds arrived at empirically in several countries.

The distribution of "general" beds is given in several of the references, particularly the Gluckman Report,³² the Australian Parliament's Joint Committee on Social Security, "Sixth Interim Report,"³³ and the British Hospital Surveys.³⁴ The population required to support adequate facilities in such clinical specialties as malignant diseases, neurosurgery, plastic surgery, thoracic surgery, etc., range from one to two million, as noted in the Australian report, the British Hospital Surveys, and the master plan of the Hospital Council of Greater New York.³⁰ The British have tentatively set up the following special service standards for a 2,000,000 population unit:

| | |
|--------------------------|--|
| 1 Radiotherapist | per 130 beds |
| 1 Thoracic surgeon | per 60 beds in tuberculosis institutions |

The institutional facilities required to remove the third major lag in medical care, referred to above, have recently begun to be explored. The principle that beds for mental, chronic, and rehabilitation services should in general be associated with general hospitals is the chief development.^{23, 33} The specific requirements for mental facilities are best set forth by Blacker,³⁵ the American Psychiatric Association,³⁶ and the U. S. Public Health Service.³⁷ Provision for long-term illnesses are barely in process of formulation, except for the generally accepted quota of two beds per 1,000 population.^{38, 39} The most systematic

proposals are probably those recommended by the New York State Health Preparedness Commission.⁴⁰ The importance of the problem of rehabilitation is evident from the general legislative provisions in both Britain⁴¹ and the United States,⁴² particularly the former. One of the best statements of specific requirements is the Baruch Report,⁴³ amplified by Kessler in *Rehabilitation of the Physically Handicapped*.⁴⁴ Denmark was one of the earliest countries to develop rehabilitation, particularly in connection with its invalidity insurance. The law requires that individuals with disabilities which may cause loss of working ability must be referred to an invalidity insurance court, which in turn refers patients to orthopedic centers with occupational therapy departments attached.⁴⁵

The United States is well in advance in establishing standards for hospitals. Much of the credit is due to the pioneering work of the American College of Surgeons, whose *Manual*⁴⁶ and *Scoring Report*⁴⁶ repay consultation. An invaluable reference text is MacEachern's *Hospital Organization and Management*.⁴⁷ Another reference is the American Medical Association's "Essentials of a Registered Hospital."⁴⁸

Health Centers—The quality of health care in any community will eventually be determined by and through health centers. The bibliography on this type of institution reflects its evolutionary state.^{1, 20, 21, 49-56} Planning for this institution as a medical service center has progressed further in the British Commonwealth than elsewhere, and attention is drawn to the discussions of Stark Murray,⁴⁹ the Socialist Medical Association,⁵⁰ Parry,⁵³ the Society of Medical Officers of Health,⁵⁴ and particularly Gale⁵² for details of function and scope. Even the eighteen specific medical and health care services enumerated by Stark Murray fall short in that they omit essential promotive and preventive activi-

ties. The size of the population to be served may vary widely between urban and rural conditions. It will be noted that the upper limit for the former is generally given as between 20,000 and 25,000 people. Parry's 10,000 unit is determined by the volume of personal health services alone, while the chief factor in the larger unit would seem to be the optimum number of general practitioners constituting a satisfactory group, generally given as 8-10. It is generally considered that services should be available within a radius of half a mile, and it is this factor in urban areas which requires neighborhood centers radiating from divisional centers. The latter would be intermediary to the affiliated hospital. National town planning agencies have been established in a number of countries, and it is of interest to note the coincidence that populations of 10,000 are recommended for "primary" neighborhood units. Again, however, nowhere is there an example of a health center exemplifying fully the total scope envisaged eventually for this institution. The international significance of such a health center as a demonstration would quickly become evident.

The rural health center has received less consideration than the urban. The U. S. Hospital Survey and Construction Act¹⁷ provides one per 30,000 population, except in areas with fewer than 12 persons per square mile, which are to have one per 20,000 population. While not entirely comparable, it is of interest to note that Australia,³³ with its sparsely distributed rural population, aims to provide 760 centers with at most two physicians for a population of approximately 2,800,000, or one center per 3,680 persons. The proposed "workshop" of the "municipal physician" in rural Western Canada covers on the average a population of less than 3,000. A planned experimental rural health center is about to be inaugurated by the Rown-

tree Trust (York, England) for a population of 10,000. Two of the most successful medical services for rural areas are the Highlands and Islands Medical Service in Scotland⁵⁷ and the more recently inaugurated district and regional service in Tasmania.⁵⁸

The medical service concept of a health center raises the question of "group" or "partnership" clinics. Consequently, one awaits with more than usual interest the forthcoming reports on this emerging aspect of medical practice by the U. S. Public Health Service and by the British Medical Association respectively. The U. S. Public Health Service has published three preliminary reports.⁵⁹

Ambulatory Services—While considerable progress has been made as to institutional bed requirements for medical care, there are surprisingly few data, as may be noted in the bibliography,⁶⁰⁻⁶³ on the facilities and personnel required for good ambulatory medical or, better still, health care services. And these few are limited to "demands" as distinct from "needs" for services. One may well query whether "needs" will be definable before scientific disciplines of social physiology and of pathology have established norms and deviations as base lines for satisfactory ambulatory services. In the meantime, one may expect increasingly accurate measurements of "demands." A significant step toward the latter is the new international classification of causes of morbidity.⁶⁴ When medical school hospitals, such as those of New York University, Johns Hopkins, and the regional teaching hospitals in Britain, are associated with prepaid medical care population units, it is anticipated that one of their chief lines of investigation will be to determine demonstrable standards for adequate medical and health care, including preventive and particularly promotive health services. Requirements for the two latter are now mainly on an

empirical, if not an out and out hypothetical, basis.

3. Medical Personnel—Numbers and Training—The rapid advances in medical knowledge, and particularly technology in the past quarter century, have brought into existence auxiliary medical workers supplementing physicians, dentists, and pharmacists. These are considered essential to adequate medical care. Apart from nurses, they now include both medical and psychiatric social workers, dietitians, occupational therapists, physical therapists, medical record librarians, medical and dental laboratory technicians, x-ray technicians, and dental hygienists. The United States and Canada are the only countries in which the qualifications and registration of each type of auxiliary medical worker are as well controlled as in the practice of medicine and dentistry. Other countries regulate one or more categories, but not all, and in several countries some categories are entirely lacking. Despite extensive legislation, there will not be adequate medical care in any country until auxiliary workers are provided in sufficient numbers and their training and supervision well organized.

Nursing is so far the only profession in which numerical requirements have been determined from job analyses. The estimates for other groups are determined to a greater or lesser extent on an empirical basis. Those for pharmacists, physical and occupational therapists (except in the mental field), medical record librarians, and practical nurses have not been determined even empirically. A considerable bibliography has developed for the other professions, particularly for physicians.

The following figures, with the exception of English^{34, 35, 71} and Australian³³ estimates on physicians, are from United States sources. The most informative United States references are "Measuring the Community for a Hospital,"⁶⁵

PHYSICIAN REQUIREMENTS

| Mean | Population |
|---------------------------------|------------|
| 1 General practitioner | to 1,500 |
| 1 Surgeon | to 10,000 |
| 1 Eye, ear, nose and throat | to 15,000 |
| 1 Internist | to 30,000 |
| 1 Gynecologist and Obstetrician | to 20,000 |
| 1 Pediatrician | to 30,000 |
| 1 Roentgenologist | to 60,000 |
| 1 Pathologist | to 100,000 |
| 1 Urologist | to 65,000 |
| 1 Orthopedist | to 100,000 |
| 1 Dermatologist | to 100,000 |
| 1 Psychiatrist | to 100,000 |

NOTE: Physician's services are calculated at the rate of 2,000 hours per annum.

DENTAL REQUIREMENTS

| Mean | Population |
|-----------------------------|-----------------------------|
| Dentists | 99 per 100,000 ^a |
| X-ray Technicians | 27 per 100,000 |
| Hygienists | 45 per 100,000 |
| Laboratory Technicians | 18 per 100,000 |

* Provided there is an auxiliary staff. Lee Jones is the authority for this estimate.

*The American Hospital*⁶⁶ and the American College of Surgeons *Hospital Standardization Scoring Report*.⁴⁶ The figures presented are no more than an approximate mean of available empirical estimates. The general purpose is to draw attention to the need of basing legislative planning on estimates of personnel requirements. These figures are not to be taken as recommendations. Also, it is obvious that personnel requirements must vary considerably from country to country. Requirements in specialized fields will differ from those in the general medical and surgical fields and are not presented in this general discussion. Estimates are given in the cited bibliography. The important point to be borne in mind in formulating requirements for personnel is that increasing coördination of services and group practice, made possible through growth of prepayment for medical care, will result in a decrease of the present requirements because of the greater efficiency

NURSING REQUIREMENTS

*The Manual of the Essentials of Good Hospital Nursing Service*⁷⁰ suggests methods of measuring norms for staffing a ward unit.

1. The average number of bedside nursing hours required per patient during each 24 hours:

| | Hours |
|--|-------|
| Medical, surgical, and mixed, ward and semiprivate | 3.2 |
| Maternity, ward and semiprivate.. | 4.2 |
| New-born, ward and semiprivate.. | 2.3 |
| Infants, ward and semiprivate.... | 5.5 |
| Older children, ward and semiprivate | 4.3 |
| Communicable disease, ward and semiprivate | 4.7 |
| Mixed, private patients..... | 5.4 |
| Maternity, private patients..... | 6.5 |

2. The relationship of graduate bedside nursing hours to student bedside nursing hours:

| | Per cent |
|--|----------|
| Medical, surgical, and mixed, ward and semiprivate | 31 |
| Maternity, ward and semiprivate.. | 51 |
| New-born, ward and semiprivate.. | 61 |
| Pediatric, ward and semiprivate... | 12 |
| Communicable disease, ward and semiprivate | 37 |
| Mixed, private patients..... | 91 |
| Maternity, private patients..... | 86 |

3. The number of patients per day supervisor:

| | Patients |
|--|----------|
| Medical and surgical, ward and semiprivate | 70 |
| Maternity, ward and semiprivate.. | 67 |
| New-born, ward and semiprivate... | 82 |
| Pediatric, ward and semiprivate... | 47 |
| Medical and surgical, private patients | 62 |
| Maternity, private patients..... | 50 |

which follows planned and coördinated services.

Other interesting data than those tabulated in this study indicate that in the medical hospital an average of 6.7 staff nursing hours were required per operation, 46 per cent of which were graduate hours and 54 per cent student hours; and, that, moreover, there was a ratio of one head nurse to 5.5 operations and of one supervisor to 15.7 operations.

The type of patients admitted influ-

ences the nursing ratio. Hospitals caring for ambulant, convalescent, and chronic patients may give adequate care on the basis of a ratio as low as one nurse to 60 patients, although this is exceptional. In the extremely active hospital a ratio of 1 nurse to 1, 1½, or 2 patients may be necessary.

OTHER ANCILLARY PERSONNEL REQUIREMENTS

- | | |
|--|--|
| 1. Medical Social workers | 1 per 200 general hospital admissions or 2,000 outpatients (per annum) |
| 2. Psychiatric Social Workers | 2 or 3 to each psychiatrist or 1 per 500 outpatients (per annum) |
| 3. Dietitians | 1 to each 100 occupied beds |
| 4. Clinical Laboratory and X-ray Technicians | 1 to each 100 beds |
| 5. Occupational and Physical Therapists | (Estimated only for mental and rehabilitation. See references.) |

Requirements of public health personnel for the United States and Canada are discussed in *Local Health Units for the Nation*.⁷²

Training and Registration of Personnel—The following standards for the training and registration of personnel are drawn entirely from United States sources, which, because they are more comprehensive, best serve the illustrative purposes of the paper. Wherever equal or higher standards of training and registration prevail, the United States illustrations will not be relevant. Certain British references are included^{73, 74} as useful in countries which have not yet evolved minimum standards of training and of registration.

The American Medical Association is responsible for continuous revision of minimum essentials with respect to acceptable medical schools,⁷⁵ approved graduate schools,⁷⁶ internships,⁷⁷ resi-

dencies and fellows,⁷⁸ basic science instruction in residencies,⁷⁹ and approved examining boards in specialties.⁸⁰

The American Dental Association is responsible for minimum essentials with respect to acceptable dental schools,⁸¹ internships and residences,⁸² schools for dental hygienists and technicians,^{81, 83} and approved examining boards.⁸⁴ Similarly, the American Council on Pharmaceutical Education has set standards of accreditation of Colleges of Pharmacy.⁸⁵

Standards for nursing are controlled by the National League of Nursing Education.⁸⁶

The most recent category of personnel to emerge, for which training for accreditation is now being systematized, is the hospital administrator. The diploma covers one year of academic work and one year of supervised hospital practice. The minimum requirements for the former have not as yet become standardized, but a suggested manual for the hospital year has been worked out.⁸⁷ Registration is with the American College of Hospital Administrators, whose requirements are still entirely on an *ad hoc* basis.

The training requirements for other categories of medical care personnel can conveniently be tabulated. Each has a national association responsible for setting minimum standards and for registration. An exception is the National Association for Practical Nurse Education, which is in process of establishment.⁸⁸⁻⁹⁰

The Committee on Professional Education of the American Public Health Association is responsible for periodic revision of qualifications for the following categories of public health personnel; health officer,⁹² medical administrator,¹⁰⁰ school physician,¹⁰¹ public health dentist,¹⁰² industrial hygienist,¹⁰³ public health nurse (including industrial),¹⁰⁴ health educator,¹⁰⁵ public health laboratory worker,¹⁰⁶ public

TRAINING REQUIREMENTS (U.S.A.)

Auxiliary Medical Workers

| <i>Profession</i> | <i>Prerequisite</i> | <i>Training</i> |
|---|---------------------|--|
| 1. Medical ⁹¹ and Psychiatric Social Workers ⁹² | 4 years' college | 1 academic year, graduate 1 year practice |
| 2. Dietitians ⁹³ | 4 years' college | 1 year practice |
| 3. Occupational Therapists ⁹⁴ | 1 year college | 2 academic years' theory 1 year practice |
| 4. Physical Therapists ⁹⁵ | 2 years' college | 1 year |
| 5. Medical Record Librarians ⁹⁶ | 2 years' college | 1 year theory and practice |

THE PATTERN OF TOMORROW

The foregoing trends furnish us glimpses of the pattern future health services will undoubtedly assume. Any economic barrier to adequate medical care will be removed through either voluntary or compulsory insurance. The distribution of health care will be increasingly improved through institutions in regional areas based, as far as possible, on teaching hospitals, integrated with non-teaching hospitals and health centers. A two-way flow from the health center at the periphery to the teaching hospital at the base will assure (a) adequate social and clinical pathological diagnostic services throughout the area; (b) routine continuation education for all categories of personnel in hospitals of more than 50 beds, which for physicians would imply teaching ward rounds, central pathological conferences, special teaching clinics, as well as adequate libraries and records; and lastly, (c) graduate instruction for designated categories of personnel. Adequate services for chronic, disabled, and psychosomatic patients will have been attained.

In the future the general practitioner will find it increasingly to his advantage to practise in groups in health centers providing diagnostic facilities and ancillary personnel, as well as ready consul-

tation with fellow practitioners. As already recommended by several national medical associations, the family, rather than the individual, will be the unit of practice. A reoriented medical education will extend the practice of the general practitioner beyond his present clinical diagnosis and therapy to include most of the personal health services now rendered by health departments. He also will be responsible for prescribing measures required for the protection of the individual and of the community against such forces as interfere with development and maintenance of full mental and physical capacity.

The chief factor in rapid establishment of this pattern is the degree of aptitude of the medical profession, and especially of the general practitioner who serves as the quarterback of the medical team, in providing community family health care. The development of this aptitude requires the reorientation and extension of medical education to include social as well as clinical pathological diagnosis. A trend toward integrating social environmental and clinical instruction is already discernible. Some 27 schools in the United States now have varying degrees of clinical integration, in the manner which has already been described. Although a great step forward, this integration is too often of a negative nature because the activities practised are

limited chiefly to steps taken after disease occurs. Few relate to health promotion. The latter, generally speaking, cannot be undertaken effectively until there is prepayment in some form to provide promotive, preventive, and rehabilitative services.

Also, the rapidity with which medical education becomes reoriented will depend on the extent to which social medicine is accorded the same academic recognition and facilities for investigating and teaching social physiology, pathology, and therapy that is now provided for clinical physiology, pathology, and therapy. The immediate problem in reorientating the future general practitioner is to give him the same level of clerkship and internship in social as in clinical medicine.

The prime essential is, therefore, the provision of the health care facilities in a community as much under professorial administration as are the clinical laboratory and hospital facilities in other fields. The availability of medical school-controlled health centers is as essential for the teaching of social medicine as hospitals are for clinical medicine. In this respect there are two significant developments taking place in the United States. Medical schools are organizing themselves to promote comprehensive health care on a prepayment basis to groups in the community, and at the same time making the group clinics available for teaching purposes. The inauguration of the Health Insurance Plan of Greater New York has led New York University to establish a group clinic to provide comprehensive medical care. Other schools in New York are planning to follow suit. Recently medical care of the indigent in Maryland was transferred from Welfare to the State and Baltimore City Health Departments. The two medical schools in Baltimore are organizing health centers within their premises to provide health care to the people in their own areas.

Because the English Health Act provides for a comprehensive medical service on a prepayment basis, a unique opportunity is arising to explore and demonstrate the positive aspects of health care. Two medical centers in England are now experimenting in regard to control of the medical care facilities in their adjacent communities, including health centers. These two institutions are the Department of Social Medicine and Public Health at the University of Manchester and a group associated with London University. A University Health Center Planning Committee has been established under the chairmanship of the London School of Hygiene, associated with University College Hospital and the Child Health Institute, together with the London County Council and the British Medical Association. It is of interest to note that, at a recent meeting of an informal group of British professors of medicine, this health center requirement for the teaching of social medicine was discussed in considerable detail. A tentative conclusion reached was that one general practitioner and his team of required ancillary workers should be available for each clerk or intern in social medicine.

With the components of the general pattern clearly emerging here and there, the time in several countries is ripe for a further consolidation. The pump is primed. This was not true even ten years ago. The universal establishment of this pattern of health care as a "social science in the service of society" would usher in a new and momentous era in human welfare.

The April issue will be the Annual Special Book Issue. Dr. Huntington Williams, Health Commissioner of Baltimore, contributes an article entitled "The Health Officer's Book Shelf." There will be more book reviews than ordinarily and many announcements from publishers of newer books for public health workers.

Watch for the April Book Issue.

Experience of Rheumatic Patients Who Served in the Armed Forces, 1942-1946*

MAY G. WILSON, M.D., J. W. PAYSON, AND
ROSE LUBSCHEZ

*New York Hospital and the Department of Pediatrics,
Cornell University Medical College, New York, N. Y.*

WHEN war was declared in 1941, the patients under continuous medical supervision in the New York Hospital Children's Cardiac Clinic sought our advice as to eligibility for service. The majority of the 268 rheumatic patients of military age were eager to enter the services. It was our practice to offer a summary of the clinic record to each

patient. Of the men who volunteered or were drafted, 62 per cent (167) were accepted. Most of these men denied their past history and made every effort to pass the physical examination. The majority of the 101 patients who were classified as 4F presented their past record at the induction center.

In Table 1, A and B, there is sum-

R.F.-RHEUMATIC FEVER
B.E.-BACTERIAL ENDOCARDITIS
A.F. AURICULAR FIBRILLATION

* REGRESSION OF MURMURS OF VALVULAR LESIONS
** INCLUDES ONE DEATH
*** FLUOROSCOPIC EXAMINATION IN P. A. AND
OBLIQUE VIEWS

* This study was aided by a grant from The Commonwealth Fund.
Presented on June 7, 1947, American Rheumatism Association Meeting.

marized the past rheumatic history and cardiac diagnosis for 242 men. It will be noted that all of these men had rheu-

matic fever and rheumatic heart disease. In the service group 23 per cent had one or more attacks of active carditis with failure. In about one-half of the service group and one-third of the civilian group, the physical signs of valvular lesions had regressed. As might be expected, in the civilian group the past rheumatic history was more severe and the resultant cardiac damage was of greatest degree. In this group 43 per cent had one or more attacks of active carditis with failure during childhood.

A continuous close contact was maintained with the men in service by frequent personal letters. In addition, home visits were made for exchange of information. The majority of the patients returned for clinic visits during furloughs and after discharge from the service. The civilian group remained under routine medical supervision.

The distribution of the men in the various branches of the armed forces

and at primary and secondary training camps in the United States is summarized in Table 2 and in Figure 1.

TABLE 2

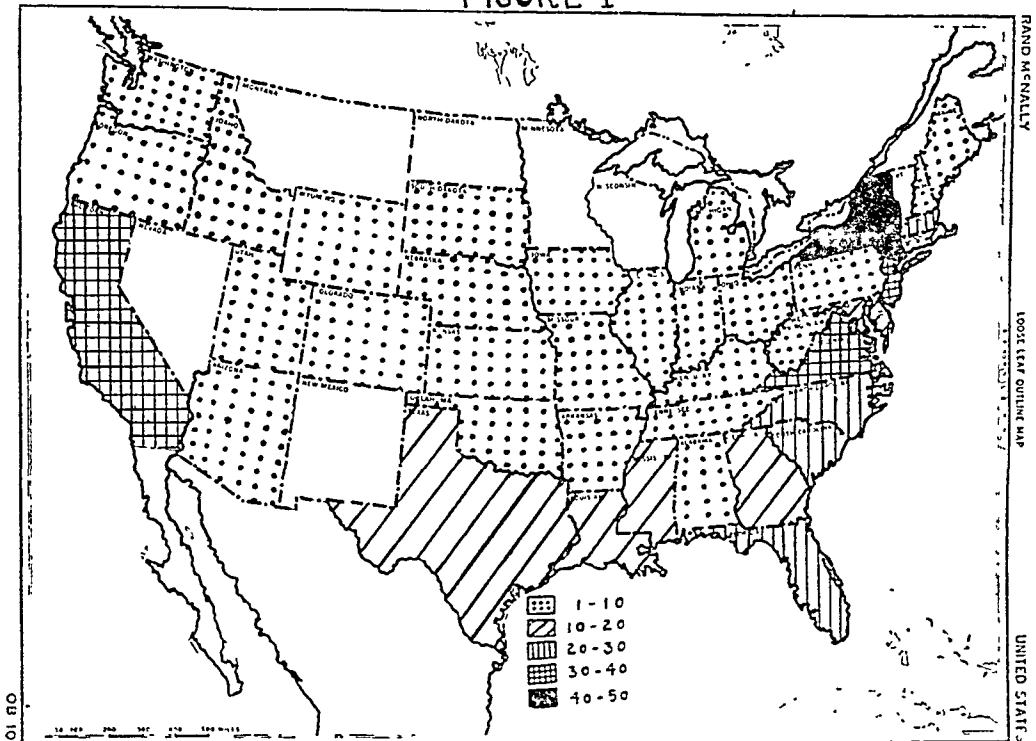

*Distribution of 141 Men in Various Branches of Service **

| <i>Branch of Service</i> | <i>Number</i> |
|--|---------------|
| Navy | 49 |
| Coast Guard, Merchant Marine | 10 |
| Marine Corps | 12 |
| Army | |
| AAF | 26 |
| Signal Corps, Engineers, Chem. Warfare, Communications | 15 |
| Infantry, Tank, Tank destroyers, Anti Tank | 26 |
| Ordnance, Anti Air, Coast and Field Artillery | 12 |
| Quartermaster, Cook, Clerk, Medical Corps | 12 |
| Amphibious Forces, Paratroopers, OSS | 3 |
| Not specified | 4 |

* Individuals may be represented in more than one branch of service.

It is apparent that the majority of the men were under considerable physical stress and experienced various climatic exposures. Seventy-eight per cent were

FIGURE 1

sent overseas and 47 per cent were in active combat. In Table 3 distribution

TABLE 3

*Distribution of 141 Men in Various Theaters of Operation **

of the men in various theaters of operation is presented.

During 386 patient-years of service, the morbidity experience in the United States and overseas is summarized in Table 4. Here it may be seen that, ex-

TABLE 4

cept for the low incidence of rheumatic fever, the various illnesses were not significantly different from Army and Navy morbidity reports.

A comparison of the incidence of rheumatic fever among our patients in serv-

ice and at home revealed that 3 men were hospitalized for rheumatic fever while in the armed forces. In the civilian group during 402 patient-years, there were 7 patients with recurrent attacks, of whom 1 died. In addition, 2 patients had bacterial endocarditis and 2 developed auricular fibrillation. It is noteworthy that cardiac failure, bacterial endocarditis, and auricular fibrillation did not occur among the men in the service. Of particular importance is the observation that among the men who returned to the clinic since discharge, no change in physical signs or cardiac enlargement was observed. Two of the patients who developed rheumatic fever in 1945 are still in military hospitals. The third patient returned to the clinic for examination. No evidence was obtained to indicate further cardiac damage.

The high incidence of rheumatic fever (about 40,000 cases) among Army and Navy personnel would appear to indicate that the circumstances of military service impose a greater risk than civilian pursuits for recurrent attacks of rheumatic fever.

It has been reported that about 50 per cent of the men who developed rheumatic fever in the armed forces had a previous rheumatic history. According to Provision MR 1-9, a history of rheumatic fever without a recurrence within two years was not disqualifying. It is therefore probable that a relatively large number of rheumatic subjects were inducted.

Although the actual number of rheumatic subjects inducted into the armed forces is not known, an approximate number may be estimated. Using data obtained from Selective Service Headquarters, the Office of the Surgeon General, the Bureau of Medicine and Surgery, and the National Research Council, the number of rheumatic subjects in the armed forces was estimated and the number of rheumatic recurrences ex-

† Average experience reported in various services.

‡ Based on the assumption that the number of man-years in service is 70% of total man-years available for induction. (Value from Selective Service.)

** $17,384,700 \times 2.8\% = 499,810$ rejected for rheumatic heart disease, based on cardiac clinic figures 499,810 = 38% of rheumatics available for induction. 62% of available rheumatic subjects were inducted

§ Based on a civilian recurrence rate of 4%.

pected in this group was calculated.

In making these analyses, it must be emphasized that the data released to us were not final reports, and that it was necessary to make certain assumptions which may not be entirely justified.

For these analyses, the following assumptions were made:

1. That the number of rheumatic subjects accepted and rejected by the armed forces was consistent with our clinic experience; i.e., 62 per cent were accepted and 38 per cent rejected.

2. That the incidence of rheumatic individuals in the population available for induction could be estimated as either 2 per cent, 3 per cent, or 4 per cent.

3. That the average civilian recurrence rate of 4 per cent, which was obtained in New York City for major recurrent attacks in this age group, is applicable to the men in service.

Analysis of Selective Service Data: About 17 million men were examined,

of whom 30 per cent were rejected for all defects; 5.7 per cent were rejected for cardiovascular defects. Reexamination of about 4,000 men revealed that on an average, 50 per cent of the cardiovascular rejectees had rheumatic heart disease. That is, about 500,000 men with rheumatic heart disease were rejected. If the proportion of rejectees and inductees from our cardiac clinic is representative, about 800,000 rheumatic subjects may have been inducted. In New York City we would expect about 33,000 recurrent attacks for this age group. About 40,000 cases of rheumatic fever have been reported for the men in the armed services.

Analysis of the Army and Navy Data:

The total man-years in the services from 1942 to 1945 represent 70 per cent of the man-years in the population which was available for induction (30 per cent were rejected). Therefore the pool from which the service group was drawn represents 49 million man-years.

The incidence of rheumatic subjects available was calculated as 2 per cent, 3 per cent, and 4 per cent of this pool. The mean value, i.e., 3 per cent, receives support from the incidence of rheumatic heart disease rejectees reported by selective service. On the assumption that 62 per cent of these subjects were inducted, an estimated pool of 600,000 to 1 million rheumatic man-years in the service is obtained, of whom 4 per cent would be expected to have a recurrence.

The total number of recurrent attacks ranged from 24,000 to 48,000, depending upon the estimated population incidence. Thirty-nine thousand cases were reported by the National Research Council for the Army and Navy.

The closest agreement between expected recurrences and reported cases was obtained when the population incidence was assumed to be 3 per cent.

Comparable analyses were made for the Army data alone and the Navy data alone. These revealed that the predicted recurrences were greater than the observed cases in the Army, assuming a 3 per cent population frequency for the disease, although the agreement on the basis of a 2 per cent incidence was good. For the Navy data, it is apparent that the number of expected recurrences was underestimated, regardless of the population frequency assumed.

SUMMARY AND CONCLUSIONS

1. Two-thirds of the rheumatic patients of draft age in the Cardiac Clinic were accepted in the armed forces.

2. The incidence of rheumatic fever (major recurrent attack) among 141 rheumatic patients in the armed forces was less than 2 per cent for 386 patient years.

3. The incidence of recurrence among 101 rheumatic patients rejected for service was 7 per cent for 400 patient-years.

4. Men with rheumatic heart disease were able to tolerate strenuous activity in basic training and under combat conditions.

5. If the assumptions made are valid and within the limitations of the data available for analysis, it appears that the majority of the attacks of rheumatic fever reported in the services were recurrences.

6. Our own limited cardiac clinic experience indicates that the risk for a recurrent attack of rheumatic fever is no greater in the services than in civilian pursuits.

Salmonella from Dogs and the Possible Relationship to Salmonellosis in Man*

ARTHUR H. WOLFF, D.V.M.,† NORMAN D. HENDERSON,
B.S., AND GRACE L. McCALLUM, B.S.

*Bureau of Disease Control and Bureau of Laboratories, Michigan Department
of Health, Lansing, Mich.*

RELATIVELY little information is available concerning the occurrence of Salmonella in dogs. Bruner and Edwards¹ have identified four Salmonella types from 18 outbreaks among dogs, namely: *S. typhimurium*, *S. choleraesuis*, *S. anatum* and *S. newport*. Edwards² maintains that these dogs were almost invariably affected with enteritis and in some cases whole litters of pups died of enteritis and septicemia. Van Dorssen³ describes enteritis in puppies experimentally produced by feeding *S. enteritidis* var. *dublin*. Stafseth⁴ reports a septicemic outbreak caused by *S. choleraesuis* in a litter of pups. *S. bredeney* and *S. newington* have also been reported from canine septicemia by Dolman⁵ and Castelo,⁶ respectively. Seligmann⁷ alludes to the isolations of *S. anatum* and *S. panama* from dogs. Reitler⁸ describes a peculiar disease observed in Palestine among dogs living in groups. The disease appeared to be associated with tick infestation. It either produced a fatal septicemia or ran a chronic course with rash, cough, anemia, and neuritic symptoms. From these outbreaks a new Salmonella type possessing the antigenic formula VI, XIV, XXIV . . . r-1.7. was isolated. Shirlaw⁹ dis-

cusses *S. typhimurium* infection of dogs in India. Newman¹⁰ isolated *S. give* from a dog affected with diarrhea of over a month's duration.

Of public health interest are several Scandinavian reports in which outbreaks of human Salmonella infection were shown to be epidemiologically related to Salmonella infections among dogs. Kauffmann¹¹ reports an outbreak of gastroenteritis involving six members of a family of seven and the family dog. *S. glostrup* was isolated from the feces of all members of the family and from the blood of the infected dog. Although the origin of infection was not determined, it was assumed that the sources of infection for man and dog were identical. Caspersen¹² reports a case in which an infected dog was the source of a paratyphoid outbreak involving six human beings. *S. paratyphi B* was the causal organism isolated from the human cases. The diseased dog was incriminated as the source on the basis of the clinical history and analytical serological tests. Another instance in which the dog was considered the source of a human paratyphoid outbreak is described by Magnusson.¹³ The causative organism, isolated from the involved dog and human beings was *S. abortus-canis*.¹⁴

Because of the possible public health significance of canine salmonellosis a study was initiated by this department to determine to what extent dogs may

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

† Division of Veterinary Public Health, U. S. Public Health Service.

serve as hosts for the Salmonella group and to determine the clinical manifestations these organisms may produce in dogs.

The dogs examined in this study were from three sources: the Michigan State College Veterinary Clinic, Lansing Animal Shelter, and a private kennel. This paper gives the preliminary results from bacteriological examination of 100 dogs. Eighteen of these animals were found to be excreting 16 different Salmonella types.

METHODS

In the present study, fecal specimens were collected by means of a rectal swab technique adapted from that described for human beings by Hardy.¹⁴ One hundred and sixty-eight fecal specimens were collected from 100 dogs. The swabs were dropped directly into tetrathionate broth and incubated for 18–24 hours at 37°C. Following incubation, 0.1 ml. was streaked upon SS agar. The glass rod used for streaking was carried over to the second SS plate to obtain a less heavily seeded plate. Poured bismuth sulfite plates with 0.1 ml. of inoculum were also used. However, these appeared to offer no additional advantages and were discontinued. The SS plates were incubated for 24 hours at 37°C. Non-lactose-fermenting colonies were inoculated into Hajna's triple sugar slants. Proteus organisms were eliminated on the basis of urease activity, using the medium of Rustigian and Stuart.¹⁵ Growth from triple sugar slants showing Salmonella-like* reactions was tested with polyvalent Salmonella serum. Those cultures agglutinated by the serum were sent to the Salmonella Typing Station† where identification was made on the basis of biochemical reactions and antigenic analysis.

RESULTS

Table 1 summarizes the data on rectal swabs collected and cultured from 74 dogs at the Michigan State College Veterinary Clinic and the Lansing Animal Shelter. Repeat specimens from these dogs were usually unavailable. The animals are grouped in Table 1 according to their clinical conditions. Five of the 38 "Distemper" dogs yielded Salmonella organisms: *S. typhimurium* was isolated from two of these dogs, and *S. newport*, *S. manhattan* and *S. minnesota* (monophasic) were each isolated once from distemper cases. All of these cases exhibited enteritis of varying degrees. The eight dogs grouped under "Gastroenteritis" were animals with a primary condition of gastroenteritis and no known history of any predisposing or incitatory factors. The one positive dog from which *S. oranienburg* was isolated appeared normal at the time of collecting the specimen but 24–36 hours later exhibited a severe diarrhea persisting for 2 days. A repeat specimen 10 days later was negative. Included in the "Normal" group were "boarders" and "strays," all appearing clinically well, at the Veterinary Clinic and Animal Shelter. No Salmonella were isolated from these normal dogs.

The monophasic variety of *S. minnesota* in Table 1 was recovered from a dog with a 3 months' history of intermittent fever and diarrhea. The animal had never fully recovered from what had originally been diagnosed as distemper. This particular case led to the investigation of the private kennel from which this dog originated. The word "kennel," in this instance is perhaps a misnomer. It was found that 25 to 30 dogs were housed with three human beings in a small three room dwelling. As might be conjectured, disease was rampant among the dogs. Distemper, enteritis, and septicemia were continually decimating the animal population of the household.

A total of 94 fecal specimens, taken

† Fecal specimens from which these organisms were isolated were collected between dates of series IV and V

x = No specimen collected

As can be observed in Table 2 the most frequently isolated type from the kennel was *S. oranienburg*. This organism was recovered from six dogs. Repeat isolation of this type was only demon-

organisms have not yet been officially named. They appear to be monophasic varieties of *S. tel-aviv* and *S. illinois*, respectively.

The bacteriological findings recorded

in Table 2 present an incongruous picture. Not only were repeat isolations relatively few but in several instances (Dogs C, E, F, and G), subsequent examinations resulted in the finding of one or more *Salmonella* differing in type from the preceding isolations. In addition, more than one *Salmonella* type was recognized in single stool specimens of dogs L and F.

The pathological significance of these

Salmonella organisms for this kennel is obscure. The kennel owner claims that almost the entire kennel was affected with septicemia, distemper, or enteritis at one time or another during the 6 months prior to our investigation. Fecal specimens taken from two of the kennel members during sieges of diarrhea were negative for *Salmonella*. Post-mortem bacteriological examinations of two 6 week old puppies affected with hemor-

* Septicemia refers to any of the following clinical pictures: enteric (or paratyphoid) fevers; generalized septicemia and/or localized septic manifestation.

† Mesenteric lymph nodes of apparently healthy swine.

rhagic enteritis were negative for *Salmonella*.^{*} Moreover, all of the dogs from which *Salmonella* were isolated, with the exception of A and B, were clinically normal at the time of our examinations. Both dogs A and B died of enteritis and septicemia, and post-mortem bacteriology of dog B revealed no *Salmonella*. A blood specimen was obtained from dog F from whose feces five different *Salmonella* types were isolated. The culture of the blood was negative. Agglutination tests were performed with the serum against each of the five types recovered from this dog. The highest demonstrable titer was 1:40 with *S. bredeney*.

In view of the incongruity of the *Salmonella* isolations from this kennel and in view of the kennel's decidedly substandard sanitation, it was thought that the food or drink might be affording a means of "reinfection." No *Salmonella* could be isolated from the water. However, both the well and cistern gave a high coliform index. Water samples taken from the common watering bowl yielded only *Proteus* strains which might indicate fecal contamination. Of the food included in the ration, eggs seemed to be the most likely source. All eggs consumed by these dogs were rejected candled eggs from a local market. Eggs from the local market and the supply stored at the kennel have been cultured. To date, only *S. pullorum* has been isolated.

DISCUSSION

It is difficult to assess the pathological significance of these *Salmonella* types for dogs on the basis of this limited study. The combined data from the Michigan State College Veterinary Clinic and the Animal Shelter indicate some association of these organisms with distemper or enteritis, or both. On the other hand, the kennel findings sug-

gest the possibility that these kennel dogs were transient carriers. In any event it appears that the dog may serve as a more frequent host of *Salmonella* than has been thought in the past.

Table 3 illustrates some previously reported occurrences of the *Salmonella* types identified in this study. The 16 types recognized in this work are serologically, biochemically, and morphologically similar to those frequently infecting man, birds, and other animals. Consequently an epidemiological relationship may exist between dogs, birds, man, and other animals. To the writers' knowledge, of the types found in this work, only *S. give*, *S. bredeney*, *S. newport*, and *S. typhimurium* previously have been reported from dogs. On the other hand, all of the 16 types have been isolated as suspected pathogens from human beings with the possible exceptions of those organisms with the antigenic formulae III,XV:z₁₀—and XXVIII:y.

SUMMARY

The following *Salmonella* types have been recovered from dogs by other workers: *S. typhimurium*, *S. choleraesuis*, *S. anatum*, *S. newport*, *S. panama*, *S. give*, *S. bredeney*, *S. newington*, *S. paratyphi B*, *S. abortus-canis*, *S. glossstrup*, *S. enteritidis* var. dublin and a type closely related to *S. carrau*. Most cases manifested enteritis with septicemia occurring as a frequent sequel.

A study has been started to collect data pertaining to the incidence and significance of *Salmonella* organisms among dogs. Stool specimens were collected by rectal swabs from 100 dogs. Tetrathionate broth and SS Agar were used routinely for isolation procedures. *Salmonella* types were recovered from the stools of 18 of the 100 dogs examined. The following types were identified: *S. manhattan*, *S. newport*, *S. minnesota* (both monophasic and diphasic varieties), *S. oranienburg*, *S.*

^{*} The immediate cause of death in both pups was ileal intussusception.

typhimurium, *S. bredeney*, *S. worthington*, *S. give*, *S. cubana*, *S. cerro*, *S. kentucky*, *S. illinois* and *S. meleagridis*. There were two types isolated to which the antigenic formulae of XXVIII:y and III, XV:z₁₀ respectively were ascribed.

The pathological significance of these isolations has not yet been entirely ascertained, and additional work is being performed toward this end. However, this work does indicate that the dog may be a frequent host for the *Salmonella* organisms. In view of the established pathogenicity for man of most of the above cited *Salmonella* organisms, the dog should be considered as a potential source of *Salmonella* infection for man.

ACKNOWLEDGMENT: The authors wish to express their appreciation to Dr. P. R. Edwards of the *Salmonella* Typing Station, University of Kentucky, Lexington, Ky., for his assistance in confirming some of the *Salmonella* types identified in this work.

Problem of Dust Control for the Disinfection of Air*

FROM the standpoint of control, all air-borne diseases, with few exceptions, may be considered to take place "indoors" where people congregate, and the bacterial and viral content of the intramural environment attains an infective level. Whether pathogens in "droplet nuclei" as defined in the report of the Subcommittee for the Evaluation of Methods of Control of Air-borne Infections¹ are more important in the spread of air-borne diseases than dust-borne organisms from "environmental reservoirs" on floors, clothes, and bedding; has not been determined. Irrespective of the size of the droplets in which bacteria are expelled from the respiratory tract, the majority relatively soon settle and become components of dust.² Several studies, which have been published in the past year, have added much information concerning the relative importance of the methods of dispersal of respiratory disease agents in the air and the immediate environment. It seems important to summarize the results of these studies briefly.

Dispersal of respiratory disease agents into the environment: Duguid,³ employing *Erythrobacillus prodigiosus* as the tracer organism, found that speaking, coughing, and sneezing produced many droplets small enough to remain air-borne as droplet nuclei, and that essentially all of these droplets origi-

nated from the front of the mouth. The extent of air-borne infection which may occur from droplet nuclei then must depend on the frequency with which pathogenic organisms occur in the secretions in the anterior mouth. Examining 85 scarlet fever, 50 faucial diphtheria, and 20 open tuberculosis patients, he found, respectively, small numbers of hemolytic streptococci, diphtheria bacilli, and tubercle bacilli in the anterior mouth secretions of only a small portion of the individuals in each group.⁴

Studying the size of droplets expelled by sneezing, coughing, and talking by microscopic measurement, Duguid⁵ found that they ranged in diameter from 1 to 2,000 microns, the most common being between 4 and 8 μ . The proportion of droplets of each size which contained bacteria, whether commensal or pathogenic, was determined by the size of the droplets and by the number of bacteria in the secretions atomized. Calculations made on the basis of size distribution showed that few of the smaller droplets and, thus, fewer droplet nuclei are likely to contain organisms. He concluded, therefore, that droplet spray is unlikely to give rise directly to air-borne infection unless very large numbers of pathogenic organisms are present in the secretions of the anterior mouth. In undisturbed air of a 1,700 cu.ft. room, Duguid found that 90 per cent of the bacteria carrying droplet nuclei disappeared by settling in from 30 to 60 minutes; particles larger than 8 μ disappeared in 20 minutes, while smaller particles remained suspended for a longer period of time. When the air

* Referee's Report on Suppressive Measures for the Control of Dust, to the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents. Committee authorized 1941. Published Reports, *A.J.P.H.*, May, 1943, Aug., 1944, Aug., 1945, Apr., 1946, and Apr., 1947.

was disturbed by a fan, the bacteria disappeared at a much faster rate.

Hare and associate have extended their observation on the mechanism of spread of bacterial and certain virus infections of the respiratory tract.⁶ They confirmed their earlier observations and those of Duguid³⁻⁵ that the number of organisms expelled varies according to the type of respiratory activity, and concluded that only by "violent and impolite" methods (sneezing) can a carrier of a pathogen infect the atmosphere of his vicinity to any great extent directly from his mouth or nose. They point out that the path which organisms take after leaving the nose and mouth will likewise vary with the particular activity but will, in general, be downward and forward. The site of impingement of the great majority of particles is on objects below the level of the head, resulting in the direct contamination of the immediate environment of the donor by his nasal and buccal secretions. As these extruded bacteria can be raised again and again into the air as dried particles, Hare considers these dust-borne agents responsible for conveying infections to others.

The recent studies of Hamburger and coworkers⁷⁻⁹ support the findings of Duguid³⁻⁵ and Hare.⁶ These investigators found that persons with positive nose cultures for hemolytic streptococci extruded many more of these pathogens into their environment than did those with positive throats alone. By far the greatest number were expelled by blowing the nose, although some individuals dispersed hundreds and millions of streptococci, respectively, by coughing and sneezing. In wards housing these individuals only an occasional hemolytic streptococcus could be recovered from the air during quiet periods; whereas, during periods of bedmaking and floor sweeping large numbers were recovered from the air.

From their studies, Hamburger and

associates⁹ concluded that the extensive streptococcal contamination of the environment took place somewhat as follows: The act of blowing the nose and sneezing contaminated the handkerchief and, simultaneously, the hands, with a few streptococci escaping into the air. From the handkerchief, the dried nasal secretions containing hemolytic streptococci are dispersed into the air and settle out as dust. The contaminated hands provide the opportunity for transfer of microorganisms to personal clothing, bedclothes, and anything with which they come in contact. Thus, by these routes the environmental surfaces and air may become markedly contaminated with pathogens; this would probably be the usual situation where streptococcal disease was epidemic in hospital wards, boarding schools, orphan asylums, and military barracks and schools. They further conclude that direct hits by streptococci expelled by unprotected sneezing, coughing, or talking, or the inhalation of droplet nuclei containing streptococci dispersed by these activities undoubtedly account for a certain number of sporadic infections, but they are probably of secondary importance in the epidemic spread of streptococcal disease.

Hodges and MacLeod recently reported an extensive study on epidemic pneumococcal pneumonia in an army camp.¹⁰ The presence of specific pneumococcal types throughout the population was uniform and pneumonia occurred in all parts of the camp. Airborne dissemination of pneumococci among the personnel appeared to be a likely explanation of this epidemiological picture, for it was found on culturing the dust in the schoolrooms and barracks that a high percentage of the samples were positive for pneumococci. The types found in the dust reflected directly the prevailing types of pneumococci in the throats of carriers, supporting the earlier work of Stillman.¹¹

Little is known concerning the mech-

anisms of the spread of virus diseases of the respiratory tract. In all probability they are air-borne, and because of their small size as compared to bacteria may well be carried in droplet nuclei. At the same time, they may be dispersed as dust-borne agents. Influenza virus A is known to be resistant to drying and will survive in the environment for several days.¹² Recent studies of laboratory outbreaks of Q fever strongly incriminate infected dust-borne particles as the means of dissemination.^{13, 14}

While investigating the problem of air hygiene in dressing rooms for burns or major wounds with a new sampling device, Bourdillon and Colebrook¹⁵ found that large numbers of bacteria were liberated when dry bandages and wool were removed from a patient. Likewise, large clouds of bacteria often containing pathogens were liberated by the movement of pajamas or other bedclothes that have been used for some hours. Their data confirm the observation of others that unsoiled blankets should not be allowed in any surgical dressing room.

New apparatus for measuring particle size: There is a tremendous range in the size of droplets expelled in mouth and nose secretions during talking, sneezing, coughing, blowing the nose, and spitting, and the final size of droplet nuclei or dust-borne particles capable of carrying pathogens is not accurately defined.¹⁶ Knowledge of the range of particle size of dust containing bacteria which are dispersed into the air during bedmaking and floor sweeping would be most helpful in evaluating the importance of dust-borne bacteria in the spread of respiratory disease. Hatch¹⁷ reviews the problem of the behavior of microscopic particles in the air and in the respiratory system. Studies show that particles larger than $5\ \mu$ are removed primarily in the upper respiratory tract while progressively smaller particles are deposited in the more distal

parts of the bronchial tree and alveoli.

These findings are supported in a recent study by Davis.¹⁸ Employing the rabbit as the experimental animal, he found that droplets above $7\ \mu$ were all removed by the nose during inhalation. About half the $3\ \mu$ diameter drops penetrated the lungs and practically all those $1.5\ \mu$ and smaller.

Most instruments utilized in the collection of dust particles for size measurement employ a single jet or slit and a single stage for deposition of the dust. Recently a new instrument called "the Cascade Impactor," for sampling liquid and solid aerosols has been described by British workers.¹⁹ Because this apparatus seems applicable to the study of the size range of naturally dispersed droplet nuclei and dust-borne particles carrying bacteria in a given atmosphere, a brief description of it is given. This instrument is suitable for sampling wind-borne and stationary aerosols such as natural fogs and clouds, fine sprays, insecticidal mists, coarse dusts, pollen, and spores, etc. By means of four progressively finer jets impinging on glass slides in series the sample is split up into size-graded fractions in a form suitable for microscopic analysis. The greatest efficiency of sampling is achieved for particles in the diameter of range 50 to $1.5\ \mu$. The size-grading greatly facilitates the detailed microscopic examination of heterogeneous samples and in some cases enables approximate size-distributions to be obtained by bulk estimations of the samples without the need for microscopic sizing. A complete description with diagrams and photographs of the apparatus and results of sizing aerosols of certain liquid and solid materials is given.

Recently, Sonkin²⁰ has described a modified cascade impactor for sampling and sizing aerosols of particles below $1\ \mu$ in diameter. He was able to separate clouds containing particles of glycerol water, methylene blue solution

below $1\ \mu$ into different size classes permitting rapid and convenient size characterization of the aerosol. In discussing the question of the use of the cascade impactor with Sonkin, he states that it can be readily adapted to the study of size range of naturally dispersed bacterial particles (droplet nuclei and dust-borne particles).²¹

Landahl and Block,²² studying the penetration of air-borne particles through the human nose have also employed the cascade impactor. Employing corn oil, sodium bicarbonate, and tricalcium phosphate, they studied the effect of particle size and flow rate through the nose. They found that (a) in the case of corn oil droplets passing through the nose at 10, 17, 29, and 60 liters per minute, the particle diameters corresponding to 50 per cent penetration were found to be 8, 5, 5, and $2\ \mu$, respectively; (b) for sodium bicarbonate particles at 17 and 60 liters per minute, the diameters for 50 per cent penetration were 2 and $1\ \mu$; and (c) for tricalcium phosphate at 17 liters, the 50 per cent penetration size was $4\ \mu$.

Studies on the application of oil to floors and bedclothes for the control of dust-borne bacteria and cross-infections in hospitals: In an Australian hospital, Rountree and associate²¹ found large numbers of hemolytic streptococci in the ward floor and blanket dust and also in the dust from the floor of the surgical dressing room where the sterile trays were prepared. Sampling the ward air revealed a marked increase in the number of bacteria during bedmaking.

Rountree²⁵ found that the emulsifying mixture referred to as "Fixanol C"²⁶ containing cetyl pyridinium bromide known to be highly germicidal exhibited marked bactericidal properties for a number of Gram-positive and Gram-negative organisms. Likewise, the "Fixanol C" when incorporated in the oil-in-water emulsion imparted a bactericidal action to the emulsion. Blank-

ets treated with "Fixanol C" and oil became bactericidal and retained this property for as long as 3 months. Although she found a 1 per cent water solution of "Fixanol C" non-irritating to the skin as shown by the patch test, it was pointed out that the hypersensitivity of certain individuals to bromide drugs should be borne in mind when subjecting them to the wearing of garments or sleeping in blankets treated with this oil formula.²⁶ Wright and associates³⁰ in discussing their experience with this oiling method consider the risk of skin irritation negligible.

A trial study²⁷ over a 4 month period, employing blankets oiled with "Fixanol C" without other dust control measures, was made by Rountree. No effect was observed on the incidence of wound cross-infection on a surgical ward, although the treated blankets were shown to contain almost 100 per cent fewer bacteria than unoiled ones in similar use.

Robertson²⁸ reports the results of instituting oiling procedures in the Chicago Lying-In Hospital on the bacterial content of the air in one, two, and four bed wards, operating room, birthroom, and nursery during the months of February to May, 1946. All articles of clothing coming to the hospital laundry were treated with the T-13 oil emulsion formula² with the exception of the personal clothing of internes and nurses. The percentage reduction of air-borne bacteria brought about by oiling was greatest in the rooms containing 4 patients (90 per cent) and least in single rooms (40 per cent). In the nursery where the bacterial count was lowest initially, the reduction after oiling was very slight.

In 1944, Wright and coworkers²⁹ reported a highly favorable study on the use of oiled bedclothes and floors in preventing cross-infections due to the hemolytic streptococcus in measles wards. When these methods were employed, the streptococcal (type 6) cross-

infection rate among the patients fell from 58.1 per cent during the preliminary period with oiled floors alone to 18.6 per cent when, in addition, oiled bedclothes, garments, and ward linen were used. The cross-infection rates for the same periods in the unoiled wards were 53.5 per cent and 73.3 per cent, respectively.

Recognizing the difficulty of drawing conclusions with respect to the value of dust control procedures for the prevention of hospital cross-infections from a single study, Wright and associates³⁰ carried out a similar study the following year (1945) on the measles wards of another hospital. Similar methods were employed²⁶ and a more rigid aseptic technique was instituted to reduce the possibility of other modes of spread. As was found in their previous study²⁹ the oiling methods effected a marked reduction in the total bacterial and streptococcal counts in the air of the test ward. Thus, the reduction in the mean total bacterial count and hemolytic streptococcal count of the air of the oiled wards during bedmaking was 92.3 per cent and 94.7 per cent, respectively, and during floor sweeping, 79.1 per cent and 95.9 per cent, respectively, when compared to counts obtained in the air of the control ward during similar periods of activity.

In contrast to the favorable clinical results obtained in their 1943 study, the cross-infection rate, although low on both wards in 1945, was actually higher (20 per cent) in the oiled than (12.4 per cent) in the unoiled ward. The authors found these results difficult to explain. They point out that both wards had a comparatively low cross-infection rate of the same order as the 18.6 per cent rate which was regarded as satisfactory for the oiled ward in the 1943 investigation. The low degree of aerial contamination by streptococci in both wards suggested that the cross-infections were caused by a mode of spread which

was not air-borne. Two factors are presented which possibly explain the higher cross-infection rate on the test ward—(a) a higher admission rate of type 12 streptococcus, the only streptococcal type which showed signs of “communicability” and “virulence,” and (b) a higher admission rate of skin sepsis and streptococcal otorrhea cases.

The absence of a markedly virulent “communicable” strain of streptococcus on the wards in the 1945 study was in striking contrast to the condition on the wards in 1943. In the latter investigation, only one group A streptococcal type (type 6) was responsible for the high cross-infection rate and complications on both wards before and on the control ward after oiling methods were instituted. In the 1945 study, numerous types and groups of hemolytic streptococci were isolated from the cases of cross-infection. Thus, the conditions favorable for the spread of streptococci in measles wards vary from one epidemic year to another.

Wright and her coworkers conclude “that the results of the 1945 investigation need in no way discourage further trials of dust suppression by oiling. Should unfavorable conditions of 1943 recur in subsequent measles epidemics, dust control may again assume importance as a measure of preventing infection.”

SUMMARY AND CONCLUSION

1. Recent studies suggest that the indirect spread of respiratory tract infections from the inhalation of dust-borne bacteria is more important than by the direct inhalation of infectious droplets or droplet nuclei. The relative importance of droplet nuclei and dust-borne particles in the spread of virus infections is not known. More exact knowledge concerning the size range of dust-borne particles and droplet nuclei containing bacteria and viruses is essential to evaluate further methods for

the control of infections spread by the air-borne route.

2. An apparatus for sizing liquid and solid aerosols has been reported. This instrument, or a modification of it, appears to be adaptable to the study of size ranges of naturally dispersed droplet nuclei and dust-borne particles carrying bacteria and viruses.

3. Recent studies confirm the results of earlier investigations^{2, 23} that to oil floors and bedclothes for the control of dust-borne bacteria is a highly efficient procedure. The use of the T-13 oil emulsion formula for the treatment of bedclothes with oil in a civilian hospital has been demonstrated. The incorporation of germicidal agents into oil-in-water emulsions to increase their efficiency merits further study.

4. Two studies by the same investigators have been reported which show that in 1943, dust suppressive measures effected a marked and significant reduction in the incidence of cross-infections due to a highly communicable strain (type 6) of hemolytic streptococcus on a measles ward; but in 1945, when the incidence of cross-infections due to numerous types and groups of streptococci was low, no effect was observed. Likewise, in another study, oiling blankets with a germicidal oil-in-water emulsion did not reduce the incidence of secondary infections of burns in a surgical ward.

5. The studies reviewed in this report point up the fact that no respiratory tract infection, whether of bacterial or virus etiology, and no wound or burn infection is acquired only by the air-borne route. The opportunities for spread of respiratory tract infections or of developing secondary infections of wounds and burns by other means than through the air in an environment highly contaminated with infectious dust are many. Direct contact with some object or person in the environment may assume a role of major importance in some situations.

FRUITS OF THE PRINCETON CONFERENCE

THE fact that approximately one-third of the population of the United States lives in areas which lack the essential services of a full-time health officer has long been a subject of concern to our Association. Dr. Haven Emerson's Subcommittee on Local Health Units has provided us with full data on this point, has suggested definite and practical ways in which this vital health need of the nation could be met, and has fought gallantly for the cause for the last five years. During the past six months public interest in the subject has at last been aroused on a wide scale, and the promise for future progress is now bright.

A Conference was held at Princeton last fall under the auspices of the American Public Health Association which brought together representatives of 65 national citizens' organizations representing some 50,000 local and state branches whose membership constitutes a large part of the adult population of the country.¹ At this Conference, the representatives of these agencies discussed the findings of the *Subcommittee on Local Health Units of the Committee on Administrative Practice*²; the citizen agencies present, by resolution, urged their respective agencies to use all their influence to get complete coverage of the nation with health units of such area and population as to be economically efficient and justifiable.

Since September, the published *Proceedings of the Princeton Conference*³ (as well as four special bulletins of information) have been sent to the participating agencies. The National Health Council—as the appropriate body representing voluntary citizen participation in the health program—has accepted leadership in developing a nation-wide campaign for universal full-time health service. Its first major step was the calling of a planning meeting in New York on January 23. To this recent Conference, 47 of the Princeton agencies sent delegates at their own expense. They voted that a national advisory and coördinating committee be created under the National Health Council which would develop programs, educational materials, hold regional meetings, and give staff advisory service to local committees and councils seeking to extend local health services. Resolutions of the Conference⁴ state “that the goal is to obtain complete coverage of all states and all communities by local full-time health units under competent professional direction.” They ask:

That the National Health Council be requested to create a National Advisory Committee on Local Health Units composed of responsible representatives of interested organizations.

That this committee seek to develop a central program advisory service, materials and such other clearing house functions as may prove desirable.

That the national organizations be encouraged to begin stimulation of state and local action to obtain the necessary local health units.

That each organization be encouraged to develop a specific program of action adapted to its structure and character.

That each organization urge its state and local affiliates to work coöperatively with existing state-wide and local coöperating agencies or councils in order that there may be a pooling of interests, planning and action in securing complete coverage.

Among the items discussed by the Conference was the increase in local full-time health service that has actually taken place since July, 1947. In the last six months of 1947, 16 new counties were brought under the umbrella of full-time local health service. This has come about by the creation of only three new health departments, because consolidation of counties or of cities and counties has been even more active than the creation of new departments. Buffalo and Erie County in New York, for example, with a population of nearly one million; Seattle and King County, Washington, with more than half a million persons, have each consolidated their health departments, as have Charleston and Kanawha County in West Virginia. South Carolina is serving the entire state with six fewer local health departments than it had six months ago. Indiana has organized the first bi-county health department in its history.

At the January meeting, the agencies represented reported a surprising degree of activity already carried out by them in furthering this plan. The national Congress of Parents and Teachers has undertaken to sponsor a federal bill providing specifically for grants-in-aid to encourage local health service. Both the National Tuberculosis Association and the National Society for the Prevention of Blindness have adopted as a part of their national platforms coöperation with other agencies in developing community health services. Some of these activities were reported in the January *Journal*⁵; others will be reported elsewhere. That there should have been such an outpouring of interest as a result of the first bringing together of representatives of the general public in behalf of extending local health units, gives us hope that the presently underprivileged third of the nation with respect to health protection may, in the foreseeable future, enjoy those minimum health services which every citizen has a right to expect from his local government.

NEW DEVELOPMENTS IN TRICKLING FILTER OPERATION

SINCE the trickling filter was developed nearly half a century ago and the activated sludge process was introduced in 1913 and 1914, there have been many useful advances in mechanical detail; but the underlying principles of sewage treatment have remained essentially stable. In the past decade, however, new concepts of the working of the trickling filter have been developed which permit a radical improvement in the efficiency of that valuable method of sewage treatment.

It has long been known that the trickling filter could operate successfully for short periods at very high rates; and it was gradually recognized that the limitation of the load which such a filter would carry was related to the clogging which results from an increase in the zoögleal films which develop on the surfaces of the filtering material.

Actually, little biochemical oxidation occurs as the liquid passes through the filter. The oxygen-demanding constituents are physically removed from the flow, accumulate on the filter media, undergo oxidation, and eventually are "unloaded."¹ In serving the dual purposes of separation and subsequent oxidation of organic material, the efficiency of the filter in removal of B.O.D. per unit volume is much decreased. In addition, older methods of surface distribution provided unequal utilization of all portions of the filter bed.

For many years it had been observed that the recycling of certain strong trade wastes through a filter increased the ultimate purification obtained.² The advantages of securing uniform distribution of the waste over all portions of the filter bed were also recognized. Realization of the importance of these principles in the treatment of municipal sewage seems to have arisen concurrently in England, Germany, and the United States during the early 1930's.

The resulting modifications of the trickling filter which have been worked out and are now available to designers, are numerous. They range from single or two-stage filtration with recirculation, developed in this country; to alternating double filtration and enclosed aerated filters, experimented with in the British Isles. Each of the suggested flow sheets may have an application under certain conditions, but each must be custom-built to the problem at hand. Together, they constitute a formidable challenge to the conventional trickling filter and the activated sludge process, and can also compete with chemical precipitation where only partial treatment is desired. This challenge is not to be interpreted in terms of treatment superiority alone, but on the basis of economy in construction and operation and of flexibility in meeting unforeseen changes in quantity and quality of sewage. The substantial ability of the conventional filter to take "shock" loads is attained at the expense of low efficiency per volume of filter during normal operation.

The development of "high-rate" filters in the United States was greatly stimulated by a 1940 report of civilian consulting engineers on sewage treatment policy at military installations. The report suggested that the new filters would provide an acceptable method of treatment in many cases, for reasons of economy, and because temporary use of the installation would minimize the importance of any unexpected difficulties which might arise due to lack of experience with the new processes.

The exhaustive study of the National Research Council on Sewage Treatment at Military Installations³ has added greatly to the knowledge of "high rate" filters as well as other types of treatment. It deserves the closest study by authorities responsible for sewage treatment in civilian communities.

At present it is estimated that over 300 communities in the United States have adopted one form or another of "high rate" filter treatment. Loadings of B.O.D. per cubic yard of media vary from 1.5 to 5 lbs. compared with 0.25 lbs. in conventional filters. For typical municipal sewage the permissible increase in loading can result in up to 90 per cent reduction in the amount of filter rock required, and major savings in the cost of filter structure and area of site. Additional costs of pumping, and of increased sedimentation capacity, to some extent reduce the savings described. Performance of the plants varies from that to be obtained

with chemical treatment to that of a well operated activated sludge plant, depending on the intent of the designer. Nitrification and bacterial removal at high loadings are less complete than with conventional filters.

In several ways, the behavior of high capacity filters is intermediate between old-style filters and activated sludge. Since biological growth is discharged continuously, without oxidation in the bed, it is greater in volume than trickling filter humus, but less difficult to digest and dewater than activated sludge. Repumping is required for circulation; and power costs are apt to be between those for conventional filters and activated sludge since the pumping of sewage against low heads is more economical than the use of compressed air.

Requirements for technical supervision vary, but in many cases are comparable to those at conventional trickling filter plants.

The contribution of industry in providing highly efficient low-lift pumps, and improved mechanisms for distribution of liquid on the filter have been an essential corollary to the improvements described. Wide experience has now been obtained with a variety of flow sheets on typical domestic sewage, on various industrial wastes and on mixtures of both.

Designers should endeavor to provide the greatest flexibility possible in these types of plants. Arrangements to change the amounts of recirculated liquid, and to pump filter or secondary effluent into the primary clarifier or to the filter should be included.

The economy of high capacity filters is of particular interest with present construction costs, which are almost 100 per cent above those of pre-war, and with many treatment plants approaching the limit of their capacity. In some cases provision of recirculation equipment alone may render it possible to increase markedly the capacities of existing filters or to compensate for insufficient sedimentation capacity.

In resort areas, or where industrial activity is seasonal, it is sometimes feasible to provide conventional filters for a low winter load which can be operated as high rate units during the greater flow and concentration of the summer.

There is also an increasing need for economical methods of industrial waste treatment to meet desired stream standards. Here too, the newer filter applications are worthy of consideration. Combinations of open earth lagoons and high capacity filters particularly merit consideration in this regard.

In Britain due to curtailment of new construction, much of the recent work has had the objective of increasing filter capacities without major changes in equipment or structures. This has necessitated the use of loadings in the neighborhood of 0.35 lbs. of B.O.D. per cubic yard which would not be classified as "high rate" operation in this country.⁴ In addition, British practice regards the production of a well nitrified effluent as desirable with the smaller stream dilution usually available there. There is also less tendency to rely on chlorination for good bacteriological results. For equivalent performance, recommended filter loadings in the two countries do not vary substantially.²

A DREAM

THE Health Officer dropped in at the Club late one afternoon (shall we say, for a cup of tea?). The Professor was in one of the two really comfortable chairs before the window, and he sank back in the other with a sigh of relief. Of course, the Professor was bound to talk—he was always talking—but you didn't have to listen.

The Professor was full of beans this afternoon. "Joe," he said, "you should have been at that meeting in Washington last week. They're beginning to make plans for a President's Conference on Childhood and Youth. We shall really have a program by then, a program which will visualize the child as a person—a human being—not a dissected jig-saw puzzle with one piece labelled 'Health,' and one 'Recreation,' and one 'Education.' We're going to put the pieces together and make a real picture."

There was a good deal more of this, and the Professor's voice was soothing. The Health Officer was tired that afternoon. He drowsed off a bit and had a dream.

He dreamed that he was sitting at the head of his conference table at the office, with eight men and two women gathered about the table. He was telling them about a recent intensive study of the boys and girls in the city's largest high school. He reviewed the physical defects revealed by this study, the lack of sound health knowledge, the emotional maladjustments and social frustrations which had come to light. He urged a real coöperative effort on the part of all the social forces which bear on the health of the child.

He asked the Commissioner of Education what could be done to build a really unified program of health education, in which the physical examination of pupils could be integrated with day-by-day instruction in the classroom. Of course, there were no conflicts between the two departments; but arbitration of grievances is not coöperative planning.

He called on the Secretary of the County Medical Society for suggestions as to what could be done to secure more complete correction of the physical defects found in school children. What could the individual physicians do to meet this situation and what should the city do to supplement their efforts?

He raised a question or two with the Director of the V.N.A. as to what its nurses in the home could accomplish in closing the gap between diagnosis and treatment and pledged his support to the Association in its effort to get more nurses and raise their salaries to a more adequate level.

He reviewed, with the psychiatrist heading the Child Guidance Clinics, the notable accomplishments of those clinics on the one hand, and their quantitative inadequacy to meet the real needs of the community, on the other.

He questioned the Commissioner of Charities as to the figures set for forming relief budgets and their relation to the actual costs of living.

He drew out from the Director of the Family Society a statement in regard to the expert counselling given in border-line households as to budgeting and management, advice which may make reasonably normal family life possible even on a substandard income.

The Commissioner of Parks and Playgrounds was called on for a statement as to the facilities for recreation which are so vital in connection with building the physical and emotional and social health of youth.

The pastor of one of the leading parishes presented his views on the indispensable contribution which the Church could make to a full-valued personality.

The Chairman of the Housing Authority was there too; and he pointed out the vital service which public low-rent housing was rendering in the rehabilitation of the home as a corner-stone of community living.

The State Commissioner of Labor and Industry happened to be in town and he contributed something on the relation of sound child labor laws to the common cause.

At this point, a heavy truck thundered by outside. The Health Officer woke up and said, "Oh well, it was only a dream!" And the Professor was still talking.

THE VIRUS OF A COMMON COLD

IT is a challenging circumstance that the commonest type of communicable disease to which the human race is subject—and the one which causes more days of disability than any other—should remain so largely a mystery. Some "colds" are probably physiological in origin, but others occur in sharply marked community epidemics. The "common cold" is probably not one disease but many from an etiological standpoint; and how closely the specific organisms concerned are related, no one can say with certainty. A very high degree of specificity of symptoms may be manifest in a given place and at a given time, while quite a different picture is presented in another epidemic.

That some infections of this type are due to filterable viruses, has been demonstrated for more than thirty years. Now, for the first time a specific virus, identified as the cause of a typical "cold in the head" has been cultivated by Topping and Atlas of the National Institute of Health.¹ This virus has been carried through seven successive passages in allantoic fluid and shows no decrease in virulence, but instead stabilization of virulence at a rather high level. Of sixty volunteers inoculated intranasally with allantoic fluids or fluids from embryonated hen's eggs; 57 have exhibited a characteristic and uniform syndrome.

This is a substantial forward step in the study of the minor, but immensely important, infections of the upper respiratory tract. The duplication of these observations by other workers in the presence of clinically similar infections should prove of the greatest importance, particularly if means can be devised for comparing the effects of the viruses isolated and their mutual immunological relationships (assuming—as common experience would suggest—that such infections are followed by a temporary state of immunity). Topping and Atlas have opened the door to a road which may lead to a real understanding of this vital health problem.

HELPING THE COMMON MAN TO UNDERSTAND

The process grows apace of bringing public health to the average man in his own language. Five recent examples are of interest:

One is "Our Neglected Insane" by George S. Stevenson, M.D., Medical Director of the National Committee for Mental Hygiene in the October 28 issue of *Look Magazine*. With more pictures than words, it tells what are the usual conditions in mental hospitals, and gives five suggestions on "What you can do to help." Number 5 of these suggestions is perhaps the most thought provoking. It is, "You can read the fourth chapter of Genesis, 9th verse, and think through the meaning of those famous words: 'Am I my brother's keeper?'"

The *American Magazine* for December, under the title "Flu Doctor," tells briefly the story of the influenza vaccine developed from fertile hen's eggs by Thomas Francis, M.D. Dr. Francis, it will be remembered, received one of the Association's 1947 Lasker Awards. The *American's* story includes a picture of Dr. Francis working in his laboratory.

Look Magazine's December issue, in "The Hospital Goes Home," tells how Montefiore Hospital in New York is sending chronically ill patients home and still providing them with modern hospital care. Mostly in pictures, this tells of a unique experiment in home care using doctors, nurses, social workers, and housekeepers.

The *Country Gentleman* for September (in its Country Gentlewoman Section) has "A Picture of Health" by Laura Lane in which the community implications of the Hospital Survey and Construction Act are explored, with particular emphasis upon what each citizen

can do about his health and that of the community.

Parents' Magazine for October, 1947, in an article, "They Eat Breakfast in Cedar Rapids," tells with suitable illustrations and typical menus how Cedar Rapids, Iowa, became "good breakfast" conscious "over-the-back-fence," as it were.

BLITHE IS BORN

"Blithe," which stands for Better Living in Illinois Through Health Education, stepped into the public health education scene in October, 1947, with Volume 1, No. 1. This is to be a monthly clearing house for the exchange of ideas, published by the Illinois State Health Department whose Director of Health Education is Margaret Cowdin. A feature of the first issue is a detailed account of the organization of the Adams County Health Council. In this county, the city of Quincy and the county are organizing a joint health department which will be in effect on a full consolidated basis by July 1, 1948.

A.D.A. FORECAST

This is the name of the new monthly publication of the American Diabetes Association, Vol. 1, No. 1, which appeared in January. It is a national magazine for diabetics and the general public giving information about diabetes and its control. The first 2 copies off the press were presented to Charles H. Best, M.D., co-discoverer of insulin, and Elliot P. Joslin, M.D., of Boston, world renowned authority on diabetes, at a special ceremony in New York on December 12.

The editor of the Journal is Elizabeth M. Mullmann, formerly editor of the Philadelphia Metabolic Society Quar-

terly which has been discontinued in favor of the new magazine. Publication office is One Nevins Street, Brooklyn 17, N. Y. Subscription price is \$2 a year, 25¢ a copy.

TEXAS HAS A PUBLIC HEALTH JOURNAL

A new member of the fraternity of monthly public health journals is the *Texas Journal of Public Health*, Vol. 1, No. 1, which first set up a lusty cry in November, 1947. This is the organ of the Texas Public Health Association which already has a history of a quarter of a century. The leading article in this first issue is "How a Health Department Functions in a Disaster," which tells how the Galveston County Health Department operated in the Texas City Disaster, "the one organization on the mainland capable of doing relief work within one hour after the initial explosion." The editor is Mary E. McNeill and the address is Court House, Dallas, Tex.

DENVER'S CAPSULE REPORT

The 30th Annual Report of the Denver Tuberculosis Society is primarily a spot map showing tuberculosis cases in the city, of which a new one is reported every 15 hours. But on the edges and the back of the map, it manages to report on 16 activities carried out during the year, on its plans for 1948, and to mention 5 items under "Here's How You Can Help," as well as to summarize its finances, thank its volunteers, and print the names of its officers. A good example of effective brevity.

MEDICAL RESEARCH ON THE AIR

A weekly "Research Report," now being used by 54 broadcasting stations, is being prepared by the National Society for Medical Research. This society, whose President is Anton J. Carlson, M.D., was organized in 1946 as an outgrowth of the New York State Medical Society's successful campaign against

the enactment of anti-vivisection legislation in that state.

The weekly 15 minute radio scripts constitute a resumé of the activities, achievement, and adventure of medical science. Nor is the material confined narrowly to activities in the United States. A recent weekly script (Research Report XVII) discussed British Anti Lewisite, the new chemical approach of Swedish Professor Holgar Hyden of the Stockholm Karolinska Institute toward the mentally ill, and a brief story of vitamins up to date, beginning with Casimir Funk in Poland and his work on beri beri in sailors. All this material should be a good antidote to the quackeries that disturb the air waves.

The society also publishes a bi-monthly bulletin devoted to the problems raised by anti-vivisection campaigns. The Jan-Feb., 1948, issue (Vol. 2, No. 3) lists a number of excellent articles on animal experimentation that have been reprinted and are available without charge. These should be of particular interest to health educators. National Society for Medical Research, Chicago 2.

STATE LEGISLATION AFFECTING PHYSICIANS

The *Journal of the American Medical Association* performs a real service for its members in summarizing in one place 1947 state legislation of interest to physicians. In the Organization Section of the November 29, 1947, issue (Vol. 135, No. 13), George E. Hall of the Bureau of Legal Medicine and Legislation, under 9 main headings such as allied professions, hospitals, foods and drugs, control of disease, and medical and hospital insurance plans, summarizes the legislation with full footnote references to the specified laws.

CONNECTICUT TAKES THE NEXT STEP

Connecticut has long had a permissive local health district law; its 1947 legis-

lative session enacted a bill for state aid to such districts. The next logical step has now been taken—a suggested plan by the State Health Department for grouping the 169 municipalities of the state into health districts, each of which would have a health center built as a part of the hospital and health center construction program.

Under this plan the state is divided into 8 hospital areas but the three alternate plans for health districts range from 28 to 31. Of the 28 districts in one plan, 13 had an estimated 1946 population of less than 50,000, 5 of less than 40,000.

The hospital and health center plans are outlined in *Connecticut Hospital and Public Health Center Survey Report* which is available from the Connecticut State Health Department, Hartford.

YOUR HEALTH DEPARTMENT

The Cattaraugus County (N. Y.) Health Department has prepared an 8 page leaflet to help residents understand and use the services of their health department. Entitled "Your Health Department," it has a picture and a short description of each of the department's activities together with a directory of the district subcenters. Emphasis is upon the services; no space is used to list important names.

CLEVELAND CATCHES RATS

Cleveland celebrated Rat Week, December 1-6, by killing off all the rats that could be found by the combined efforts of the citizens. The Junior Chamber of Commerce gave \$25 to the first person who brought in 40 rat tails, and a similar award to the person bringing in the largest number during rat week. The Cuyahoga Rat Control Organization also awarded \$25 to the professional exterminator who brought in the greatest number of rat tails. The City Health Department publicized procedures for rat proofing.

"The serious shortage of food in the world" is the first item in the reasons given for this special drive on rats.

POLIO AND PEOPLE

One of the new publications preparatory to the 1948 March of Dimes campaign is "Polio and People." It is significant for the simple and sympathetic way in which it tells what services the individual family with a polio sufferer may expect from his local chapter and what are the jobs still to be done in wiping out infantile paralysis. As such it is a useful model for other health education material. *Publication No. 66*, National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

DENTAL HEALTH EDUCATION

On the theory that children's books are especially suited to the mind and interest of children, the Georgia State Health Department makes the text and illustrations of *Frank Visits the Dentist* look and sound like a story book for small children. Short conversational sentences and brightly colored illustrations help the child to think of the dentist's visit as an interesting adventure. With the pamphlet also are book marks with five dental slogans, each reproduced in five colors. Available from Annie Taylor, Educational Director, Division of Dental Health, Georgia Department of Public Health, Atlanta 3.

PROMOTING PUBLIC HEALTH NURSING

The kit for the 1948 National Public Health Nursing Week, April 11-17, has been distributed. It is intended primarily for local committees sponsoring the "week" in local communities but also is useful in a year round program of public information. It is attractively packaged and has good promotional material with varied appeal. National Organization for Public Health Nursing, 1790 Broadway, New York 19. \$1.00 per kit.

Section Highlights of the 75th Annual Meeting

SUMMARIES of Section highlights at the 75th Annual Meeting of the Association as seen through the eyes of the Section Secretaries are shown below. It is the hope that these will bring to the many members who could not get to Atlantic City something of the flavor and content, in capsule form, of the Sections' scientific meetings. Eight of the Section secretaries have prepared such summaries. They are herewith presented, beginning with the earliest Section organized.

LABORATORY SECTION, GEOFFREY ED-SALL, M.D., *Secretary*:

The expanding scope of public health laboratory activities was strikingly illustrated by the variety of material which was discussed at the sessions of the Laboratory Section in Atlantic City. Papers on methods for detection of occult blood in the presence of iron salts, on the cell smear method of diagnosing cancer, on the use of chick embryo smallpox vaccine (on a larger scale than has been tried heretofore in this country), and a lively group of papers on various aspects of Rh typing, were representative of the range of interests to be found in the sessions of this Section.

Of special interest to diagnostic workers were reports on micro techniques for rapid identification of pathogenic organisms, on limitations of the rectal swab method for diagnosis of enteric disease, and on the latest results of a coördinated study of various gonococcus media. The meetings were also enlivened by the presentation of different points of view with regard to the best technique for identification of diphtheria bacillus.

The joint session of the Laboratory Section with the Conference of State and Provincial Public Health Laboratory Directors provided a setting for some of the most informative material that was presented at the meetings. Other joint sessions yielded information of a variety too great to be condensed in a paragraph, but among the highlights may be mentioned: a significant report on the effect of diet on susceptibility of rats to typhus; an up-to-date report of the status of the microbiology of frozen foods; a series of papers which defined and explained some of the obscure factors which determine good or bad dishwashing; a group of papers expounding the applications of statistics to laboratory procedures; and a panel of reports on the current status of immunization procedures.

Also of interest was a luncheon session—the first held by the Section in several years—at which Dr. Stuart Mudd and Dr. Robert S. Breed reported on the recent International Microbiological Congress.

Two developments of major interest to the Section with regard to standard methods should be reported: first, that Dr. Archie Robertson was able to display a galley proof of the forthcoming 9th edition of *Standard Methods for the Examination of Dairy Products*; second, that the standard methods work heretofore developed and handled by the Laboratory Section and other sections has been raised to the level of an Association activity through establishment of a Coördinating Committee on Laboratory Methods under the Committee on Research and Standards. This promises to tie together the related

activities of the various Sections in this field in a way hitherto impractical and to expedite the production of published results of the work of these committees.

HEALTH OFFICERS SECTION, JOSEPH G. MOLNER, M.D., *Secretary*:

The Health Officers Section meetings at the 75th Annual Meeting of the American Public Health Association at Atlantic City were unusually well attended and interest in the subject materials of the speakers was apparent.

An interesting panel discussion on "The Essentials of Good Local Public Health Administration" was conducted by panel leader, Dr. V. A. Van Volkenburgh. This panel was composed largely of local health officers at city and county levels and included also Dr. Carl E. Buck, Field Director of the American Public Health Association.

The panel discussed the problems that face local health officers, particularly the shortage of personnel and the inadequate training of existing personnel. Good personnel management, budgeting, and the relationship of the health department to other agencies were also discussed. Audience participation at this panel discussion was exceptionally good.

Visitors from Great Britain, Sir Andrew Davidson and Sir Allen Daley, discussed the impact of the war upon post-war public health. It was rather fascinating to learn that their problems were not greatly different from ours. Sir Allen Daley pointed out specifically that there is a definite tendency in Great Britain toward affiliating hospital with public health services.

Dr. Bruce H. Douglas, Health Commissioner of Detroit, presented the problems that face a large American city. These three speakers brought out vividly the difficulties which public health agencies in Great Britain and in this country are presently encountering and also offered suggestions as to ways

and means of meeting these problems.

An interesting paper was presented by Dr. Hart E. Van Riper, Medical Director of the National Foundation for Infantile Paralysis, on the subject, "Can Public Health Agencies Handle Poliomyelitis Alone?" He pointed out that the cost of care of infantile paralysis victims, particularly with modern methods of therapy, is almost prohibitive. Outbreaks of poliomyelitis are apt to be rather sudden and are, of course, unpredictable. Generally speaking, governmental agencies when making appropriations for public health do not make allowance for unpredictable outbreaks of poliomyelitis. He stated further that often emergency appropriations through these channels require long periods of time.

It is difficult to emphasize fully the significance of another paper presented at this session, namely, "How Much Control of Cancer?" by Drs. Earle G. Brown and Joseph H. Kinnaman of the Nassau County (New York) Health Department. The authors indicated clearly that the health agency will ultimately have as an important responsibility the problems of cancer control and cancer education programs.

The last session of the Health Officers' Section was devoted to a series of papers on Hospital Relations. Here was discussed the rôle which the hospital can play in a public health program, both through its physical facilities and through an active sharing program. The proposed and already existent hospital programs in New York State, Saskatchewan, and Indiana were described in detail, together with the practical application of combined hospital and health center programs, particularly in the Latin Americas. It appeared from this series of papers that an increasingly closer relationship is being developed between hospital and public health programs, to the advantage of both hospital and public health services.

VITAL STATISTICS SECTION, CLARA E. COUNCELL, Ph.D., *Secretary*:

The Vital Statistics Section had a varied program with discussions of many different phases of work in this field. There were two independent and two joint sessions, one with the Laboratory Section and the Biometrics Section of the American Statistical Association; and one with Epidemiology, Maternal and Child Health, and School Health Sections, and the Council on Rheumatic Fever of the American Heart Association.

The first independent session was devoted to papers on National and International Vital Statistics. These included a comprehensive summary of the major problems of vital statistics registration, by Dr. Bailey, which elicited supporting comments, especially from the registrars. In Dr. Fraenkel's paper on medical attendance during terminal illness there were some new and effective statistics to show lack of adequate medical care in the areas studied.

Dr. Linder described the machinery and accomplishments of statistical activities of the United Nations, and, in the absence of Dr. Curiel, Dr. Neurdenburg of the Netherlands reviewed the status of the proposed International Statistical Classification of Diseases, Injuries and Causes of Death, as well as some of the highlights of the recent International Statistical Conference. Dr. Hedrich presented a proposed set of rules for resident allocation which was approved by the Vital Statistics Section, to be referred to the Committee on Research and Standards.

The round table of representatives from Vital Statistics and other health fields, with Dr. Winslow performing brilliantly as panel leader, provided a helpful picture of what is needed in training for the use of vital statistics. Although some felt that the requirements suggested were certainly ambitious, there was nevertheless a high

degree of unanimity of opinion. The discussion presented opportunities for the exchange of useful ideas. It seems to be generally accepted that sound training in methods, with emphasis upon application to practical problems, and increasing use of field work are desirable.

In the business sessions Dr. Puffer, Dr. Linder, and Dr. Councell were re-elected as Chairman, Vice-Chairman, and Secretary respectively. Dr. Moriyama was elected to succeed Dr. Whitfield, whose term expired in 1947. Dr. Watkins was reappointed as Vital Statistics Section representative on the Fellowship Committee of the Association. Mr. Pennell has agreed to serve on the Committee for Membership and Vital Statistics Directory of the Section.

Dr. Densen's report, for the Committee on Remuneration and Standards, summarized the status of the study of background information and salaries of professional personnel.

Mrs. Jones reported for the Committee on Opportunities in Statistical Work that the committee hopes to acquaint qualified persons with job opportunities in public health statistics by publication of a pamphlet on "Careers in Public Health Statistics." A plan was also suggested, for Section and Association consideration, by which travelling fellowships would be made available to vocational guidance officers in colleges so that they might become informed of the activities and opportunities in the field of public health statistics.

The report of the Committee on Membership and Directory read by Miss Bellows indicated that work on the revision of the *Directory* is under way. Several professional societies have already been circularized for prospective members.

FOOD AND NUTRITION SECTION, ALICE H. SMITH, *Secretary*:

The limitation in number of sessions

from preliminary analyses of the American Academy of Pediatrics study of child health services.

The general subjects of the joint sessions were immunization, preservice and inservice training, and the rheumatic fever control program.

At the business sessions, in addition to the election of officers for the coming year, the Section heartily endorsed the proposed expansion of official Association activities in maternal and child health through the formation of a special committee, with members drawn from the several Sections particularly interested in maternal and child health. Several resolutions were introduced and four were finally approved for submission to the general Resolutions Committee. It is to be noted that three of the four were finally passed by the Governing Council and promulgated officially. The resolutions recommended: (1) support for the International Children's Emergency Fund, (2) extension of programs for the care of premature infants, and (3) repeal of specific taxes on oleomargarine.

It was pointed out that wider participation by the membership and fellowship of the Section in program planning and activities between annual meetings would make the secretary's task easier as well as make the Section itself more useful.

PUBLIC HEALTH NURSING SECTION,
ROSALIE I. PETERSON, R.N., *Secretary*:

The Public Health Nursing Section participated in two joint meetings, one with the Health Officers and Public Health Education Sections, and the Public Health Veterinarians. Mary C. Connor, *Chairman* of the Nursing Section presided as co-chairman and introduced the Public Health Nursing speaker, Marion W. Sheahan, who presented a paper on "The Public Health Nurses' Contribution in the Annual

Planning of a Public Health Program."

The other joint meeting was with the School Health, Maternal and Child Health, Public Health Education, and Food and Nutrition Sections, where Miss Connor again acted as co-chairman. Miss Ruth Freeman presented a paper on "The Contribution of the School of Nursing and the Graduate Course of Public Health Nursing," and Hortense Hilbert was a discussant representing Public Health Nursing.

The Public Health Nursing Section had a meeting of its own, in which topics that were of vital concern to nurses today were discussed, namely: "The Public Health Nurse in a Nutritional Appraisal Program" by Mary McLaughlin, "Public Health Nursing in the Cancer Control Program of the U. S. Public Health Service," by Rosalie I. Peterson, and "Field Experience Facilities in Public Health Nursing," by Helen Fisk.

In pre-war days, the Public Health Nursing Section had had its business meeting at a luncheon meeting. This was resumed this year, and approximately 300 persons attended. In addition to the election of officers, reports by the Chairman of the Standing Committees were made. These reports consisted of the one on "Administration" by Marion Sheahan, on "Education" by Ella McNeil, on "Eligibility" by Alberta B. Wilson. All three stressed the stimulation and enjoyment which they had had in serving on these committees. Dorothy Deming gave a report on "The Merit System Examination Program for Public Health Nursing." Interspersed with these reports were delightful solos rendered by a local student nurse. This program was sponsored by the New Jersey State Organization for Public Health Nursing.

A ballot had been prepared for the Nursing Section prior to the meeting which facilitated the voting. The following members were elected to office:

imposed by the Association membership at the 75th Annual Meeting was not accompanied by limitation of quality in the case of the Food and Nutrition Section. On the contrary, two outstanding sessions were held.

Dr. Johan Latsky of the Food and Agriculture Organization of the United Nations and Dr. Martha M. Eliot of the U. S. Children's Bureau, left no doubt in the mind of anyone present of the urgent need for a sympathetic understanding of the needs of people in war-torn countries. Their words, based upon personal observation, left no doubt about our moral and financial obligation to "do something about it."

The session on Methods for Appraisal of Nutritional Status brought us up to date on projects that have been under way for some time. There was considerable discussion provoked by the papers read, in fact, small groups were still "discussing" forty minutes after the meeting was adjourned.

Dr. Charles G. King reported the progress of a new committee, Sanitary Practices in Food Industries. Although the Food and Nutrition Section has assumed responsibility for the formation of this committee, the membership will consist of representatives of many other sections interested.

The Committee on Remuneration made a progress report and will continue to collect data this year.

The services of the Section Council were offered to the Association Merit System Service.

If you enjoyed the meetings, we hope you will spread the word around and encourage attendance at next year's meeting. We hope, too, that you will feel free to send the Secretary suggestions for next year's program.

MATERNAL AND CHILD HEALTH SECTION,
MYRON E. WEGMAN, M.D.,
Secretary:

The Maternal and Child Health Sec-

tion held one independent session and three joint sessions at the Annual Meeting of the Association. The independent session was devoted chiefly to problems of child development. Dr. Edith Jackson described experiences with a rooming-in project for new-born babies at the New Haven Hospital. Patients for the experiment were selected from mothers who wished to have their babies in the same room with them, a desire apparently present in the majority of mothers. There was general approval of the idea on the part of both parents and nurses despite occasional difficulties. The plan worked particularly well with primiparae.

Dr. C. Anderson Aldrich described a study of the answers to the question, "What behavior does your child have of which you do not approve?" asked of mothers of one year old children. One of the surprising results was that almost two-thirds of the mothers said that their babies did nothing of which they disapproved. This may have been influenced in part by the amount of education in child development which mothers taking part in Dr. Aldrich's clinic had had. It was also obvious that many of the things of which some mothers complained were quite unimportant.

Dr. Margaret F. Gutelius described her experiences with modified self-selection of food for preschool children in the home. On this regime, although there were occasional bizarre departures from the usual meal, the children, nevertheless, over a period of time selected a well balanced diet, grew well, and were well adjusted.

Dr. Kent Zimmerman described the beginnings of a program in the state and local health departments of California, looking toward expansion of activities in mental hygiene and preventive pediatrics.

Dr. Charles L. Williams summarized some of the statistical data resulting

Ruth Freeman, *Chairman*, Margaret S. Taylor, *Vice-Chairman*; Zella Bryant, *Secretary*; Marion H. Douglas, *Section Representative of the Nominating Committee for the Governing Council*; Mary C. Connor, *Section Council Representative for a five year period*; and Alberta B. Wilson, *Nursing member on the Committee on Eligibility*.

In addition to these sponsored programs, nurses participated in other meetings. Miss Sheahan represented Public Health Nursing in a panel discussion on "Basic Training for Vital Statistics," and Mary E. Parker discussed "Nursing Follow-up in a Rheumatic Fever Community Program." This was a joint meeting of the Maternal and Child Health, Epidemiology, School Health, and Vital Statistics Sections, and the Council on Rheumatic Fever of the American Heart Association.

I am sure that you will enjoy the opportunity of working with Zella Bryant. You will find her coöperative, stimulating, and conscientious. I shall also be able to give her suggestions and will be available for discussions. In fact, I have just prepared a memorandum of some of the suggestions which I believe will be helpful. I know that I have left the work as Secretary in good hands and I am equally sure you will enjoy working with her.

PUBLIC HEALTH EDUCATION SECTION,
REBA F. HARRIS, *Secretary*:

The 25th annual program of the Public Health Education Section grew out of the work of the membership throughout the past year. While workshop procedures characterized the entire program, a variety of conference techniques was used. These techniques provided a wide range for membership participation in such activities as: presiding at a session, a group conference or a committee meeting; asking questions, giving opinions and taking part in group dis-

cussions; mapping plans, compiling and giving committee reports; presenting formal papers; giving active consultant services in the motion picture theater, the Association press room; and rendering service in Health Education and Publicity headquarters, and in other scientific exhibits.

Through the work of the 14 committee chairmen and the Section Council a total of 118 members came to the conference with a specific assignment on the program. It is estimated that 70 to 80 per cent of others present took an active part in some phase of the work during the conference period.

Some of the highlights of the Section program were:

1. The pre-conference planning group composed of Section Council members, all committee chairmen and past officers of the Section for its twenty-five years of existence.

2. The lively business conference at a dinner session with 150 members present.

3. The 12 informal group conferences held by cross-Section and Regional committees with a combined total attendance of 1,130.

4. The two interesting joint sessions with other Sections, and the final session of four formal papers.

5. The exhibits from Hawaii and Canada with formal papers by members from these countries; the coöperative work with the National Publicity Council for Health and Welfare Services, the motion picture theater, and the Association press room.

6. The appointment of a Committee on Mechanics of the Section.

SCHOOL HEALTH SECTION, S. S. LIFSON,
Secretary:

Attendance at the meetings organized by the School Health Section reaffirms the fact that health programs related to school children continue to interest public health workers.

The reports on research projects were well received. Four studies were presented dealing with anemia in school age children, topical application of fluorides, testing for visual acuity and absenteeism in schools. Combining a business ses-

sion with reports on scientific research proved to be a good combination.

Five Sections co-sponsored a symposium on preservice and inservice preparation in health for school personnel which created considerable interest. Strong sentiment was expressed for publishing and reprinting the symposium papers as a group. The round table summary which completed the symposium was a successful innovation. Representatives designated by the sponsoring Sections discussed the papers from the point of view of their Section interests. Questions from the floor followed.

How well community resources for health education are being used in the school health program was the subject of another session. A panel composed of a county health officer, a school superintendent, and a health educator in a voluntary agency were the discussants. All agreed that health education in schools should make greater use of the health education resources of both official and voluntary agencies.

The School Health Section Council, through which the business of the Section is transacted, met often and long. Several pieces of business will be of interest to the Association membership as a whole.

1. Work was begun on drafting a set of principles to be used when legislation concerning the health program for school age children is under consideration. This is an important step forward since at each session of Congress new bills are introduced dealing with the School Health Program. These can now be considered objectively, on the basis of the principles endorsed by the Section. A committee continues this work on principles. It is anticipated that the final statement will be

one on which the several professional groups concerned can agree.

2. Ex-officio representation on the School Health Section Council was accepted by the U. S. Office of Education, the American Association for Health, Physical Education and Recreation—a department of the National Education Association, the American Academy of Pediatrics, and the American Medical Association. The School Health Section benefited materially by their counsel and experience. We wish to take this opportunity to express appreciation for their assistance.

3. The Section was pleased to learn that the National Society for the Prevention of Blindness plans to initiate a comprehensive study of vision testing procedures. At the 1946 Annual Meeting of the Association, the School Health Section Council voted to request the Society to undertake such a study.

4. The School Health Section coöperated in the Health Education and Publicity Headquarters by making consultants available to counsel with members of the Association on various aspects of the School Health Program. Ten members of the Section covered the Consultation Center. Judging from the comments heard, this was a worth while service. This service will be provided again at the next annual meeting. The School Health Section invites the suggestions of Association members on how the consultation service can be of greatest assistance.

5. The Section is indebted to two of its members for a tentative statement on the Relationships of the Voluntary Agencies to the School Health Program. After clearance with interested organizations and agencies, this statement will be widely distributed.

6. The School Health Section Council discussed ways in which its members can be involved to a greater degree than heretofore in the work of the Section. It is recognized that but a small percentage of the membership can get to the annual meeting. It is also recognized that the strength of the Section as well as of the Association is dependent upon the interest and support of the rank and file membership. A concerted effort will be made this year to engage Section members in projects of benefit to the school child.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Handbook of Psychiatry — By *Winifred Overholser and Winifred V. Richmond*. Philadelphia: Lippincott, 1947. 252 pp. Price, \$4.00.

This book is addressed to the layman. The last paragraph reads, "This book has been written in the faith that the layman wants to know more about psychiatry, and that, rightly informed, he will lose much of his dread of mental abnormalities and be willing, even eager, to join with psychiatry and mental hygiene in helping to advance the campaign for better human beings in a better world." It is a well written, clear, very superficial statement of abnormal psychology, perhaps one might say of descriptive psychopathology, but it contains little of a modern psychodynamic viewpoint. It describes the usual mental illnesses and their etiology, though in the functional psychoses and the neuroses, the etiological concepts extend beyond hereditary determination and an unhappy childhood, neither of which is presented as offering much hope of later reorganization of the personality and recovery. This interpretation of modern psychiatry is hardly in keeping with the views of the practising or outpatient psychiatrist, though it is justifiable in the light of the intramural experience of the authors. As a presentation of classical psychopathology, the book includes the usual, unproved clichés involving causality, but hedges when the issue narrows to the particular case. For example, the impression that schizophrenia is a hereditary disease is clearly stated, but at the same time the statement about whether or not persons with schizophrenic relations should marry includes the following: "If both parties are themselves healthy and normal personalities, the chances of healthy off-

spring are perhaps as good as the average." While this may be justified in a practical sense in that few clinicians have full faith in the belief that heredity is important in the schizophrenias, it is certainly not a defensible view scientifically.

This would be a good review of psychiatry for the practitioner; it is beyond the grasp of the average layman. Since its concept of mental hygiene is hardly more than implied by the term selection, it has no preventive function.

On page 142, there is an unfortunate misprint of *paranoia* for *paranoid* that is confusing at an important juncture of the development of the book's plan.

PAUL V. LEMKAU

A Survey of the Epidemiological Services in Canada with Recommendations as to Desirable Developments in the Organization and Policy of the Department of National Health and Welfare—By *D. F. Milam, M.D., and W. A. McIntosh, M. D.* Ottawa: Edmond Cloutier, 1947. 57 pp.

This interesting report represents the summation of an intensive study of the needs and inadequacies of the epidemiological services in Canada by Dr. Milam of the International Health Division of the Rockefeller Foundation. Fifteen months were spent in appraising the program then in existence in each of the Provincial Departments of Health, and the report presents recommendations for the organization of a federal Division of Epidemiology. Although preliminary efforts were made to establish such a unit in 1937, this was discontinued with the onset of war and Canada has been essentially without such service except for the functions carried out by the Laboratory of Hygiene.

The report should be of interest not only to those concerned with the coördination of federal epidemiological services but to those in the same field on the state level, since most of the recommendations apply equally well to each state health department. Of particular interest is the discussion of the relative rôles of the Laboratory and the Department of Epidemiology and the arguments pro and con as to the allocation of responsibility for epidemiological investigation, a problem which undoubtedly exists in most state health departments. The discussion and recommendations emphasize the broad applicability of epidemiological principles, not only to the field of communicable disease control but to the work of many other divisions of the health department, as well as to other governmental departments and to university research programs. It is the intent of the recommendations to create a Department of Epidemiology that will coördinate these interrelated projects.

An added valuable feature to the report is the appendix, which presents concisely chronological notes on the development of the Department of National Health and Welfare and other governmental services in Canada concerned with epidemiology. ROBERT F. KORN

Proceedings of a Conference on Industrial Ophthalmology — *Sponsored by the Columbia University College of Physicians and Surgeons. New York: Columbia University Press, 1947. 291 pp. 56 illus. Price, \$3.00.*

This book is a comprehensive post-graduate course in the peculiarities of industrial ophthalmology, its principles and professional relationships. Eyesight in industry includes a fourfold purpose—placement, protection, correction and illumination in visual acuity on the job, and consideration of the employee as a whole. It is demonstrated that a good program for the conserva-

tion and utilization of eyesight in industry requires the harmonious efforts of the ophthalmologist, optometrist, psychologist, and safety engineer—without encroachment on the practising specialist. Singular industrial population surveys reveal 15 per cent with serious eye defects; 20–50 per cent require visual help for the job assigned; only 20 per cent above 55 years pass near-point vision tests; six to eight minutes is required for screening and clinical eye tests. Other subjects such as the use of safety goggles, clear and tinted lenses for welders, basic information on illumination, e.g., contrast ratio—1:10, brightness ratios preferably 1:5 for the prevention of fatigue; use of color in the plant; industrial toxic compounds hazards and treatment and industrial first aid in chemical injuries of the eye are included. Scientific facts contributory to optimal and safe use of eyes in industry, and methods in studying the visual demands of the job are presented; research problems, including goggles for spray painting, pooling clinical information on toxicity and chemical neutralization are posed. The book is highly recommended to industrial physicians and hygienists, practising ophthalmologists, and health administrators and educators.

ROY M. SEIDEMAN

Molecules Against Microbes — *By E. S. Duthie. London, W. C. 1: Sigma Books, Ltd., 7 John Street, 1947. 156 pp. Price, 6s.*

The field of chemotherapy has long been ripe for a brief but comprehensive review; and the present volume "is an attempt to give to the ordinary man and woman a picture of how these discoveries were made." If "the ordinary man and woman" in England can follow the formulae of organic chemistry with which Dr. Duthie's volume is replete, the general reading public across the water is much better educated than on this side of the Atlantic. It seems,

however, to the reviewer that the average public health worker in the United States will find the story appealing and helpful, although such a reader may be fired by curiosity as to the almost magical processes by which the chemist determines where a particular side-chain is fixed to an organic molecule and how the chemist succeeds in attaching a desirable side-chain at precisely the right place. Dr. Duthie's simplified formulae are, however, most illuminating to the layman in organic chemistry and his illustrations (including the photograph of the actual culture plate which led Fleming to the discovery of penicillin) throw much light on the subject. Only a very few minor slips can be noted such as the statement that no cocci are motile and the author's acceptance of the old story about the Countess of Chinchon. Mrs. Duran-Reynals has shown that it was the Countess' husband who was responsible and that the tale of the lady's illness was without foundation.

It is a fascinating road upon which Dr. Duthie leads us from emetine and quinine (discovered by the indigenous natives of Brazil and Peru and introduced to Europe in the 17th century); from mercury and arsenic and atoxyl; to Ehrlich's salvarsan in 1909; the preparation of atabrin in 1933; the discovery of prontosil by Domagk in 1932 and the further development of the sulfonamide compounds; the discovery of penicillin by Fleming in 1928 and its practical development during the World War; and finally the preparation of streptomycin by Waksman in 1943.

In reviewing this story one cannot help being impressed by the outstanding contributions of German and Japanese scientists in this field; and one is again astounded that a nation so intellectually constructive as the Germans should also have qualities which lead them to forbid Domagk to receive the Nobel Prize and permitting them to re-

flood the malarial marshes of Italy prior to their retreat in the second World War.

On the whole, the development of chemotherapy during the past ten years is one of the most extraordinary chapters in the history of science. As Dr. Duthie says, "With powerful chemical weapons now at our disposal in unlimited amounts, and the prospect that others even more effective may at any moment be discovered, there is no sound reason why vast sections of the world's population should continue to live in squalor and disease, and why some of the richest regions of the world should remain in a state of only partial development. In ridding these regions of diseases which now make them dangerous if not uninhabitable for man, the chemist, biologist and doctor can play a very big part, if and when they are given the sources and facilities, often denied to them in the past."

C.-E. A. WINSLOW

Lets Talk about Your Baby—
By H. Kent Tenney, Jr., M.D. (3rd ed.) Minneapolis: University of Minnesota Press, 1947. 115 pp. Price, \$1.50.

This small book with weight charts and immunization records is a good supplement to the physician's personal contact with the father and mother of his infant patients. It is written in talkative, entertaining, and yet serious style. A thread of continuity creates personal interest in the reader's mind and is achieved by having several paragraphs in each chapter come as words from the baby's mouth. It is, therefore, easy for the reader to be sympathetic with the fundamental needs of the baby.

Of course, in such a short book some aspects of child development are omitted or only slightly touched upon. However, since the book is intended to cover only the period of infancy, no serious omissions are present. It would have been helpful to have more suggestions regarding preventive orthopedic meas-

ures. Topics that are particularly well covered are those of breast feeding, management of eating, vitamins, advice on clothing, and discussions on communicable diseases, including diarrhea. This book should be of value not only to parents but to physicians who are beginning the practice of pediatrics. One very sound suggestion to physicians is that the author indicates that he makes home visits to the baby until the infant is four months of age.

This book is an example of the leadership of practising pediatricians and their contribution to public health. Because it contains fairly specific advice on the application of new scientific developments, it is hoped that it will be revised at frequent intervals.

MARTHA L. CLIFFORD

Marriages Are Not Made in Heaven—By Janet Fowler Nelson, Ph.D., in collaboration with Margaret Heller. New York: The Woman's Press, 1947. (rev. ed.) 158 pp. Price, \$1.75.

To those individuals who believe with the author that "marriage is not a job of work, but a way of life" this little volume will be welcome. Although the book was prepared as a discussion outline for small groups of women who want further education on marriage, it contains much of interest for parents and young girls.

The author has skillfully combined the social and personal approaches to marriage, supplying material from the field of sociology, psychology, and economics in such chapters as "The Boy Friend and the Budget," "War between the Sexes," "Time on My Hands," "Speaking of Sex," and many others equally interest provoking and rich in content.

Material presented includes suggested methods for developing discussion and resource questions for participants. References are sound. Educators and par-

ents will find this of great help in their everyday approach to teaching better family living. BERNARDINE CERVINSKI

Summary of International Vital Statistics, 1937-1944—Prepared under the supervision of Halbert L. Dunn, M.D., Chief, National Office of Vital Statistics, U. S. Public Health Service, Washington, D. C.: U. S. Government Printing Office, 1947. 299 pp.

This volume was compiled and published by the National Office of Vital Statistics, U. S. Public Health Service, from data obtained during the war years to meet the urgent need for international population and vital statistics information. A wealth of material is presented with full recognition of the limitations of the data. One interesting chapter is devoted to population density in 66 countries which shows England and Wales at the top of the list with 727 inhabitants per square mile (excluding the higher densities in the Straits Settlements and in Malta) with Australia at the bottom with 2.5. The United States in this table is at 45.7 and Canada, 3.2. Other interesting tables relate to the trend of selected causes of death, including the communicable diseases, as well as longevity, marriage statistics and divorce.

REGINALD M. ATWATER

How to Interpret Social Welfare—By Helen Cody Baker and Mary Swain Routzahn. New York: The Russell Sage Foundation, 1947. 141 pp., Price, \$2.50.

Health workers in public and voluntary agencies will find this manual on methods of interpretation as applicable to their work as to the field of social work. The emphasis in this compact and meaty little book is on the "how" to interpret rather than the content of interpretation. Basic methods are presented without elaboration on the refinements or philosophy of public rela-

tions. Media commonly used by most agencies are described with explanations of how to use them directed toward staff workers and executives. The suggestions for staff discussion should prove fruitful and well worth a weekly period for a year or more. The excellent examples included should stimulate awareness of similar examples as they come along.

In the beginning of the book the authors have included a chart relating the agency to its various publics. It aptly illustrates the book's whole approach—calling attention first to the simple ways in which an agency or staff member can avoid many a blunder, and then giving helpful ideas in executing the everyday job of public relations.

MARY F. CHAMPLIN

Medical, Legal and Social Approaches to the Problems of Inebriety—*Proceedings of a Conference Sponsored Jointly by the Research Council on Problems of Alcohol and the New York Academy of Medicine, January 8, 1947, New Haven, Conn.: Quarterly Journal of Studies on Alcohol, 1947. 60 pp. Price, single copy, \$.50; 50 or more, \$.35 each.*

In the winter of 1947, the Research Council on Problems of Alcohol and the New York Academy of Medicine jointly sponsored a one-day conference which explored the medical, legal, and social approaches to the problems of inebriety. The proceedings have now been published in a pamphlet which brings up to date the present thinking with respect to alcoholism as a public health and medical rather than a penal problem.

MARTHA LUGINBUHL

Training in Clinical Psychiatry—*Symposium—By Lawrence S. Kubie, Chairman, Molly R. Harrower, Ph.D., Ed. New York: The Josiah Macy, Jr. Foundation, 1947. 88 pp. Price, \$1.50.*

Some of the most adventurous minds

in the fields of psychiatry, clinical psychology and psychiatric social work were brought together to discuss the training of clinical psychologists from the pre-clinical to the postgraduate level. This book is the report of their deliberations. The outstanding educational difficulty in the field is that of training in the clinical setting and its supervision. Clinical opportunities are too few and supervisory technics are not as clear in this field as they are in the more developed one of psychiatric social work. The place of the clinical psychologist in therapy, the relation his training has to that of the physician, the proportion of stress to be given to the psychologist as an administrator and interpreter of tests, are all discussed in considerable detail and with little concern for long-standing educational prejudices regarding the separation of the various professional groups represented at the symposium. The book will prove stimulating to those interested in training, both inservice and resident.

PAUL V. LEMKAU

Handbook of Communicable Diseases — *By Franklin H. Top and Collaborators. (2nd ed.) St. Louis: Mosby, 1947. 992 pp. 95 illus. Price, \$8.50.*

This second edition of a well known and widely used book has been expanded considerably, not in terms of appreciably more space for each disease but in terms of new chapters pertaining to diseases not covered in the previous edition and in contributions of nine new collaborators. It is still elementary, because of the necessarily brief space allotted for each disease, rather than advanced in its treatment of the subject. The new volume displays evidence of having been brought up to date as well as can be judged: (1) by spot checking on such subjects as influenza, German measles, poliomyelitis, and others; and, (2) from the references at the end of

each chapter. These indices are qualitative rather than quantitative, yet some idea may be gained from the following: The present volume is enriched by approximately a thousand new references, nearly two hundred of which refer to the twelve newly included subjects. The remaining eight hundred refer, by and large, to new material. Emphasis has varied from 98 new references for poliomyelitis and 47 for influenza to only 6 new ones for tuberculosis, and this in the face of increasing interest in BCG prophylaxis and streptomycin therapy. In the chapter on Specific Prevention of Certain Communicable Diseases, no comment was made concerning BCG.

There is no appreciable change in the arrangement and presentation of the material—after a very brief general summary of infection, immunity, epidemiology, regulations, specific prevention, serum reactions, and home and hospital management there follows, classified according to portal of entry, an orderly presentation of a number of parasitic diseases, including some helminth, protozoan, fungus, bacterial, spirochetal, virus and rickettsial diseases. The number of illustrations, both color and half tone, has been increased.

For those who found the first edition useful, this reviewer strongly recommends this new, larger and more comprehensive edition; for those who are not familiar with the book, it is recommended as a convenient and excellent digest. The index is adequate for the purposes for which the book is intended.

E. GURNEY CLARK

Practical Clinical Psychiatry.—By Edward A. Strecker, Sc.D., M.D., Franklin G. Ebaugh, M.D., and Jack R. Ewalt, M.D. (6th ed.) Philadelphia: Blakiston, 1947. 476 pp. Price, \$5.00.

This is the sixth edition of a widely used standard textbook of psychiatry. The book has been brought up to date in the light of advances made in the

field since the last edition in 1940. While the theoretical approach is in general eclectic, the predominant point of view of the authors is that of the school of psychobiology of Adolph Meyer, to whom the volume is dedicated.

In the section on classification, three types of classification are given, the genetic-dynamic classification of Adolph Meyer, the standard classification of the American Psychiatric Association, and the newer classification of the Army Medical Department. While the authors indicate that the army classification represents a step forward, the sections of the textbook are organized on the classification of reaction types used in previous editions. These are: Organic reaction types, delirious reaction types, paranoid reaction types, affective reaction types, schizophrenic reaction types, primary constitutional reaction types, and the psychoneurotic reaction types. Under each of the above headings, the authors describe the various psychiatric syndromes and provide ample illustrations with case abstracts. The discussion of treatment is brought up to date. Each section has an extensive bibliography appended relating to the subject matter of the particular section. The volume is concluded with a section on the psychopathologic problems of childhood by Leo Kanner of Johns Hopkins University. JAMES M. CUNNINGHAM

Diabetes and the Diabetic in the Community—By Mary E. Tangney, Philadelphia: Saunders, 1947. 259 pp. Price, \$2.75.

Since the survey of Oxford, Mass., by members of the U. S. Public Health Service indicated that the undiscovered diabetics of the United States added to those already under treatment may bring the total to 2,000,000 or more, a new concept of the magnitude and needs of the diabetes problem in our population has been presented.

The discovery of diabetes before the

onset of serious symptoms affords the best opportunity for early treatment and prolongation of life. The number of patients involved will tax the medical and nursing professions and require new and wholesale methods of teaching patients, as well as medical students and nurses. This new text of Miss Tangney is intended to satisfy the objectives outlined in the section on diabetes in the *Public Health Nursing Curriculum Guide* of 1942 as prepared by a joint committee of the National Organization for Public Health Nursing and the U. S. Public Health Service.

The book has many desirable features which deserve emphasis. First, the author possesses an intimate knowledge of the personal problems of diabetics, having known diabetes as a patient since childhood, and has had long experience with large groups of diabetic patients, first at the New England Deaconess Hospital in Boston and during later years as a nurse instructor for diabetic patients at the Hartford Hospital in Hartford, Conn. She stresses the teaching of diabetic patients who live in the community rather than nursing of patients confined to the hospital. The contents of the book are planned to present new aspects of the diabetes problem arising in the increasing prevalence of diabetes in the country, which is due in large measure to the advancing age and increasing duration of life of American citizens.

What is known about the etiology and prevention of diabetes is given with references to the authorities. The strictly medical data regarding the production of insulin in the body, glycosuria and blood sugar, testing the urine, administration of the insulin daily by patients, and the diabetic diet are well

presented. Separate chapters are devoted to the important complications of diabetes, including diabetic coma, arteriosclerosis and its clinical features, neuritis, nephritis, diabetes in childhood and adolescence, and particularly the problem of pregnancy in the diabetic mother. The newer data indicating that 25 per cent of the American population may be carriers of the diabetic tendency and the increasing preponderance of females among diabetics, particularly in later years, invite further investigation.

References to the literature are freely given. It is possible that the conclusion of certain authors that certain diabetics live as long as non-diabetics is not based on sufficient data, since the authors simply noted that the average age of patients studied at autopsy was about the same as that of non-diabetics. In this instance the effect of the duration of diabetes upon life expectancy did not seem to be sufficiently considered. The influence of genetic factors in diabetes is well presented in contrast to the secondary factors, such as obesity, infection, pancreatitis, and hemochromatosis.

Most useful are the chapters on diet, the teaching of diet, and the use of urine tests in relation to insulin dosage. Detailed treatment with hormones for pregnancy in diabetic mothers is given. Stilbestrol and progestin are advised on the authority of Dr. Priscilla White by intramuscular injection in small doses up to the 20th week and in larger doses during the succeeding weeks. This treatment is receiving further trial. The book is well printed and the few typographical errors hardly need be mentioned. It will help the student and graduate nurse immeasurably. The volume represents a heroic effort under great handicaps.

HOWARD F. ROOT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Evils of Bed-Rest Overdosing—We Americans invented the deadly term "Early Ambulation." Glance at the title of this British doctor's dissertation (in small type below). That should be enough to make you promise yourself to read "The Art of Plain Talk" all over again.

ASHER, R. A. J. The Dangers of Going to Bed. *Brit. M. J.* 4536:967 (Dec. 13), 1947.

We're Glad This Is Settled—This comes under the head of idle curiosity for all but bacteriologists. It seems a researcher proposed that the flagella of bacteria are not organs of locomotion, just artifacts. (It never occurred to me, in my abysmal innocence, that anyone would question such an "obvious" phenomenon.) Well, these writers took another look at some flagellated bugs in an electron microscope and concluded that the tails have the significance you, too, always thought they had.

CONN, H. J., and ELROD, R. P. Concerning Flagellation and Motility. *J. Bact.* 54, 6:681 (Dec.), 1947.

"The Day of Dull Reading Must Pass"—Here is another paper on how to prepare and read a scientific paper, but there have been so many similar treatises written without measurable effect on our annual meetings that I doubt if it's worth while to call this one to your attention, Mr. Speaker-to-be.

FELTON, J. S. The Physician and His Public Speaking. *Indus. Med.* 16, 12:569 (Dec.), 1947.

Present Status of Dental Care—From among a half-dozen findings of a study of children's teeth in several Geor-

gia communities, this one stands out most uncomfortably in my memory: there is evidence that dental caries in permanent teeth may be increasing.

HAGAN, T. L. Dental Caries Prevalence and Tooth Mortality—A Study of 24,092 Georgia Children in Twelve Communities. *Pub. Health Rep.* 62, 51 (Dec. 19), 1947.

Two Conditions Determine Outcome—Under exceptionally favorable circumstances about a thousand "well" children were given health examinations in the presence of the mother, and every reasonable effort was made to have needed medical care given to defects discovered. Half the children who should have had remedial care didn't get it. You simply must read this discussion of the reasons for the failure—if you don't, you're as hopeless as the neglectful mothers.

HARDY, M. C. Follow-up of Medical Recommendations. *J.A.M.A.* 136, 1:20 (Jan. 3), 1948.

The Prospect Is Promising—After ten years, Dr. Parran's nine basic principles for the public health control of syphilis are reviewed in the light of the progress made during the intervening decade. More than ever before, control is recognized as a medical problem to be solved by wider application of efficient case finding and medical measures.

HELLER, J. R. JR. Venereal Disease Control During the Post-War Period. *J. Ven. Dis. Inform.* 28, 11:245 (Nov.), 1947.

Keeping the Record Straight—You'll want to know about the Fulbright-Taft "Health, Education and Security Department" Bill, and what it might do if enacted into law.

HIRSCHFELD, G., and WOOD, E. M. A cabinet

Department of Health, Education and Security. J.A.M.A. 136, 2:113 (Jan. 10), 1948.

We Need To Know—If you agree that intellectual humility is a characteristic to be fostered, then you'll want opportunities to match your innocence against the depths of understanding of the experts. This paper reviews some of the things we need to find out before we can get much further along in cancer control.

Ivy, A. C. Biology of Cancer. Science. 106, 2759:455 (Nov. 14), 1947.

Premie Salvage—You are hereby reminded that premature births are a leading cause of all deaths, and the first cause of infant mortality. There is also something to be done about it. In a second paper five doctors say that caudal analgesia cuts in half the neonatal mortality among premies.

Koch, L. A., et al. Reduction of Mortality from Premature Birth, (and) Hingson, R. A., et al. Newborn Mortality and Morbidity with Continuous Caudal Analgesia. J.A.M.A. 136, 4:217 (Jan. 24), 1948.

Mid-Victorian Public Health—Although a little late in the day, your attention is directed to a paper of real historic usefulness—the last of three lectures on public health in England. In social reforms we have usually tagged along, a generation or so behind that country, so you'll find in this record the genesis of some of the "pioneering" we have done. If you ever become historically minded, you will want to review this paper.

MacNalty, A. S. The History of State Medicine in England. J. Roy. Inst. Pub. Health & Hyg. 11, 1:9 (Jan.), 1948.

Promoting Better Nutrition—Judging nutritional adequacy is a complex job involving getting a dependable record, interpreting that record, and noting frank or subtle signs of malnutrition. My

layman's guess is that this is a pretty good paper for you to read.

McLaughlin, M. A Nutritional Appraisal Program. Pub. Health Nurs. 40, 1:15 (Jan.), 1948.

Help for an Old Difficulty—Observable differences in the morphology of the viruses of smallpox, vaccinia, and chickenpox visible in the electron microscope suggest that this new instrument may prove a useful tool in differential diagnoses.

Nagler, F. P. O., and Rake, G. The Use of the Electron Microscope in Diagnosis of Variola, Vaccinia, and Varicella. J. Bact. 55, 1:45 (Jan.), 1948.

Paper of the Month—Quote. Public health officials will probably take exception to some of the ideas set forth . . . Unquote. If you don't find pleasure mixed with your exceptions when you read this wide-ranging epidemiologic discussion, then you just don't respond to nice writing. This is really a "must" for you, whatever your job may be.

Rivers, T. M. Certain Public Health Aspects of Infectious Diseases. New England J. Med. 238, 2:37 (Jan. 8), 1948.

They Seem Convinced—BCG Vaccination is a safe and effective procedure for all age groups. By the use of the multiple puncture method complications are avoided. Tuberculin conversion reaction was rapid and universal. There's a lot more beside these three quotes that you should read.

Rosenthal, S. R., et al. BCG Vaccination in All Age Groups. J.A.M.A. 136, 2:73 (Jan 10), 1948.

Out of the Mouths Department—Ways to induce people to accept guidance, is too large a subject to be covered adequately in four pages, but it is one you need to think about frequently. So here is one quotation from this brief paper, jotted down in the hope that it will inspire you to dig deeper. "I

think the reason why children don't like to follow health rules is that they take too much time and limit their fun."

STRANG, R. Motivation in Health Education. *Pub. Health Nurs.* 40, 1:11 (Jan.), 1948.

To Assuage Public Resentment—
Almost too enthusiastic to permit of

being swallowed without a tiny grain of salt is this account of the medical society's effort to "Make Colorado FIRST in Health." If the program succeeds it will indubitably earn the capitals.

SWART, C. M. Revolutionary Doctors. *Survey Midmonthly* 83, 12:331 (Dec.), 1947.

ASSOCIATION NEWS

76TH ANNUAL MEETING

BOSTON, MASS., NOVEMBER 8-12, 1948

Members of the Association are already asking about hotel rooms in Boston. On or about April 1, a hotel reservation application form will be mailed to every member and the Housing Bureau in Boston will operate on and after that date. The *Journal* will also quote hotel rates beginning with the April number.

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1948, the total membership of the Association was 11,124, including 1,913 Fellows, or 17 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine with at least one year of graduate study in public health in a University, Master of Public Health, Diploma in Public Health, or other equivalent

degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Appli-

cations are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that members themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although nearly 3,000 persons have been duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health*, usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Commit-

tee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 12 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote at the Annual Meeting for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depends upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are \$12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at \$200, covering all future annual dues.

Applications for Fellowship to be considered at the 76th Annual Meeting in Boston, Mass., November 9-12, 1948, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information address the Membership Department, American Public Health Association.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Adam N. Beattie, M. D., D.P.H., 451 Strathcona Ave., Kelowna, B.C., Canada, Director, Okanagan Valley Health Unit
- Herbert G. Cull, M.D., 2010 McClelland, Houston, Tex., Physician, Houston Health Dept.
- Matthew Dantow, M.B., D.P.H., Health Region No. 13, North Battleford, Sask., Canada, Regional Medical Health Officer
- Allan J. Fox, Town Hall, Main St., Greenfield, Mass., Agent, Board of Health
- Stillman J. Hathaway, M.D., Health Department, Court House, Chehalis, Wash., Health Officer, Lewis-Pacific District Health Dept.
- Alan D. Houser, M.D., New Paltz, N. Y., Apprentice Epidemiologist, State Health Dept.
- Edward X. Link, M.D., 213-15 So. 17th, Mattoon, Ill., Health Commissioner
- Archibald F. Mackay, M.B., D.P.H., 65 S'mcoe Street, South, Oshawa, Ont., Canada, Medical Officer of Health
- Hon. Paul Martin, LL.D., House of Commons, Ottawa, Ont., Canada, Minister of National Health and Welfare
- Samuel Minowitz, M.D., M.P.H., 1 St. Pauls Court, Brooklyn 26, N. Y. District Health Officer, City Health Dept.
- Harriet N. Rogers, M.D., M.A., Box 106, Lucedale, Miss., Director, Southeastern Health District
- Silas C. Rutland, M.D., West Central Region, State Health Dept., Griffin, Ga., Medical Director
- Edward M. Thompson, M.D., M.P.H., 212 North Upper St., Lexington, Ky., Health Officer and Director of Field Training, Lexington-Fayette County Health Dept.

Laboratory Section

- Lawrence D. Blitzer, Y.M.C.A., 215 W. 23rd St., New York. N. Y., Bacteriologist, Synchem Corporation
- Horace A. Kelley, Apartado 16, Montemorelos, N. L., Mexico, Laboratory Technician, Montemorelos Hospital and Sanatorium
- William H. Mair, 101 Central Avenue, Westfield, N. J., Director, Clinipath Laboratories
- Clara V. McWhirk, Fitzgibbon Memorial Hospital, Marshall, Mo., Director of Laboratories
- Virginia L. Pipe, 5660 Kingsbury, St. Louis 12, Mo., Senior Assistant Bacteriologist, St. Louis Public Health Laboratory

- Bill J. Reed, Municipal Laboratory, Mason City, Iowa, Laboratory Technician
- Zana G. Skidmore, M.S., Oklahoma A & M College, Stillwater, Okla., Asst. Professor of Bacteriology
- Marie S. Slawson, 2135 N. E. 45th, Portland 13, Ore., Bacteriologist and Parasitologist, Emma M. Howe Medical Laboratory
- Benjamin Q. Ward, M.A., 110 Montgomery, Laramie, Wyo., Asst. Bacteriologist, Univ. of Wyoming
- Ruth Winchell, M.A., Rt. 1, Box 1755, Portland 6, Ore., Chemist, Emma M. Howe Medical Laboratory

Vital Statistics Section

- Dorothy H. Johnston, 1085-43rd St., Oakland, Calif., Senior Public Health Analyst, State Department of Public Health
- Mrs. Wilson B. Purser, 219 Millsaps Ave., Jackson, Miss., Secy., Vital Statistics Division, State Board of Health
- Edgar G. Titus, Sc.D., 128 State Capitol, Salt Lake City, Utah, Director, Division of Vital Statistics, State Department of Health

Engineering Section

- Charles R. Barden, M.S., 1414 Lavaca, Austin, Tex., Public Health Engineer, Texas Public Health Training Unit
- Paul Bierstein, World Health Organization, P.O. Box 1477, Addis Ababa, Ethiopia, Sanitary Engineer
- John Kam'nski, Sears, Roebuck & Co., Dept. 817, 925 S. Homan Ave., Chicago 7, Ill., Merchandise Testing and Development Laboratory
- Samuel C. Olmstead, City Hall, Moberly, Mo., Sanitation Inspector, Health Dept.
- Jacob Samarjian, 631 Bay St., Santa Monica, Calif., Sanitarian, Los Angeles County Health Dept.
- Millard E. Smith, C.E., I.I.A.A. c/o American Embassy, Lima, Peru, S. A., Chief Engineer and Associate Chief, Field Party, Institute of Inter-American Affairs
- Leon W. Weinberger, S.M., Graduate House, Mass., Inst. of Tech., Cambridge 39, Mass., Research Asst.
- George E. Welty, Ph.G., 1251 So. Bronson, Los Angeles 6, Calif., Principal Sanitarian, City Health Dept.

Food and Nutrition Section

- Helen M. Amos, 515 South 31st St., Omaha 5, Nebr., Student, Univ. of Michigan School of Public Health
- Dorothy M. Kiely, M.S., 406 Orange St., Wilmington, N. C., Nutrition Consultant, State Board of Health
- Ahbrohm X. Rossien, M.D., 8415 Beverly Road, Kew Gardens 15, N. Y., Consultant Gastroenterologist
- Malcolm R. Stephens, 1211 New Post Office Bldg., Chicago, Ill., Chief, Chicago Station, U. S. Food and Drug Administration

Maternal and Child Health Section

- Hedvig H. Holzer, M.D., 591 Morton St., Dorchester 24, Mass., Child Welfare Physician, State Dept. of Public Health
- Lula J. McNeil, Route 3, Box 455-A, Norfolk, Va., Public Health Nurse, State Dept. of Health
- Bertrand Primeau, M.D., 227 Aspinwall Ave., Brookline 46, Mass., Student, Harvard School of Public Health

Public Health Education Section

- Catherine Beermann, R.N., B.S., 77 Wheeler Ave., Westwood, N. J., Director, Northern Bergen Nursing Service
- Douglass R. Hayes, 1376 N. Kenmore St., Arlington, Va., Chief of Graphics, U. S. Public Health Service
- Sol. Levy, M.D., Eastern State Hospital, Medical Lake, Wash., Clinical Director
- Earle G. Lippincott, M.A., Russell Sage Foundation, 130 E. 22 St., New York 10, N. Y., Research Associate
- F. Mack Moore, P. O. Box 76, Cathedral City, Calif., Deputy Health Officer, Riverside County Health Dept.
- Amalia Rivera, Direccion General de San'dad, San Salvador, El Salvador, C. A., Asst. Health Educator, Division of Health Education
- Max Whitman, M.A., 51-63 Stuyvesant Place, Staten Island 1, N. Y., Health Education Asst., New York City Health Dept.
- Dora H. Young, M.A., State Capitol, Helena, Mont., Secretary, State Narcotics Education Commission

Public Health Nursing Section

- Frances M. Avery, R.N., 510 E. Kilbourn Ave., Milwaukee 2, Wis. Instructor, Marquette University College of Nursing
- Eva K. Belflower, R.F.D. No. 2, Tifton, Ga., Emergency Nurse, State Dept. of Public Health

- Agnes C. Cooley, 5307-64th St., Maspeth, N. Y., Student, New York Univ.
- Christie T. Corbett, 12 Fordonia Bldg., Reno, Nev., Director, Division of Public Health Nursing, State Dept. of Health
- Elizabeth G. Eckert, Neighborhood League, 119 W. Wayne Ave., Wayne, Pa., Supervisor of Nurses
- Elaine Goben, R.N., M.S., 1221 Sherman St., Denver, Colo., Advisory Nurse, Division of Crippled Children, State Dept. of Health
- Charlotte Hasselbusch, 637 Ingraham St., N.W., Washington 11, D. C., Educational Director, Instructive Visiting Nurse Society
- Virginia M. Lloyd, R.N., 701 London St., Portsmouth, Va., Public Health Nurse, State Health Dept.
- Ruth G. McDonald, R.N., B.S., Apt. C, 2011 Flower, Bakersfield, Calif., Supervising Nurse, Kern County Health Dept.
- Anne R. Ohlbaum, 780 Grand Concourse, New York, N. Y., Director, Eastchester Public Health Nursing Assn., Tuckahoe, N. Y.
- Ione L. Ripley, American Embassy, Lima, Peru, Chief Nurse, Office of Inter-American Affairs
- Kathryn A. Robeson, M.A., 1949 McGraw Ave., New York, N. Y., Administrative Asst. and Consultant, Visiting Nurse Service of New York.
- Frances E. Shelley, R.N., B.S., 810 Chalfonte Drive, Alexandria, Va., Public Health Nursing Consultant, U. S. Public Health Service
- Helen R. Swedburg, R.N., B.S., 824 Harris Ave., Woonsocket, R. I., Director, Woonsocket Public Health Nursing Assn.
- Louise B. Thomson, 207 Shepard St., Chevy Chase, Md., Supervisor, Instructive Visiting Nurse Society

Epidemiology Section

- Domingos Barbosa-Carvalho, M.D., M.P.H., Caixa Postal No. 47, Manaus, Amazonas, Brazil, Health Officer, Special Service of Public Health
- Sidney B. Clark, M.D., M.P.H., 1302-32nd Ave., San Francisco, Calif., Medical Officer, Acute Communicable Disease Service, State Dept. of Public Health
- Mary K. Dunlap, D.V.M., 2316 Ward St., Berkeley, Calif., Veterinarian
- John S. Hathaway, M.D., 109 College, New Haven, Conn., Asst. Director, Yale Dept. of Health
- Mildred A. Morehead, M.D., 44 Allandale St., Jamaica Plain, Boston, Mass., Student, Harvard School of Public Health
- Norman Plummer, M.D., 140 West St., New York 7, N. Y., Medical Director, New York Telephone Co.

Julius S. Prince, M.D., Wildcliff Road, New Rochelle, N. Y., Physician-in-Training, State Dept. of Health

School Health Section

5. Director, Maternal, Child Health and Crippled Children Section. Salary \$4,800-5,500.

Apply at: State Civil Service Commission

314 State Capitol
Denver, Colo.

Fellowships for the Training of Health Educators

Fellowships leading to a Master's Degree in Public Health in the field of Health Education are again being offered this year to any qualified United States citizen between the ages of 22 and 40. Funds are available through a grant from the National Foundation for Infantile Paralysis.

Candidates must hold a Bachelor's degree from a recognized college or university at the time the application is filed, and must be able to meet the entrance requirements of the accredited school of public health of their choice. Proof of acceptance at such a school must be furnished before applications are submitted to the Fellowship Awards Committee for consideration. In addition to the Bachelor's degree, courses in the biological sciences, sociology, and education are required. Training in public speaking, journalism, psychology, and work in public health or a related field is considered desirable.

The fellowship consists of 8 or 9 months' academic work, which begins with the fall term in 1948, and three months of supervised field experience in community health education activities in a local health department. The academic training includes courses in public health administration, epidemiology, public health and school education, problems in health education, community organization, information techniques, and others.

Veterans are encouraged to apply, and will be paid the difference between their subsistence allowance under the G-I Bill of Rights and the monthly stipend of \$100 for single veterans or \$150 for married veterans. Employees of state or local health departments are not eligible, since federal grants-in-aid are provided through the states for such training.

Information and application blanks may be obtained by writing to the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

Public Health Workers Needed for European Rehabilitation Program

We need two qualified public health physicians; six public health registered nurses, one chief nurse to organize programs; one health consultant capable of setting up training schools for practical nurses; two nurse educators to head these schools; three medical social workers; and two public health dentists. All personnel must enlist for eighteen months. They must have physical stamina, be adaptable and sympathetic. A knowledge of Yiddish is necessary. Interested applicants should apply to the Health Committee of Joint Distribution Committee, 270 Madison Avenue, New York 16, N. Y.

NEWS FROM THE FIELD

FIRST NATIONAL CONFERENCE ON FAMILY LIFE

The first National Conference on Family Life has been called in Washington May 6-8 at the request of 110 major national agencies. The movement which resulted in plans for this meeting began in 1944 when the American Home Economics Association first discussed the need for a conference on family life. The National Planning Association joined in efforts to bring together such a group. A general steering committee with the financial backing of the Woman's Foundation in June, 1946, resulted in an agreement by more than 100 coöperating groups to request the President that such a conference be held at the White House.

Eric Johnston, President of the Motion Picture Association of America, and Boris Shishkin, Economist of the American Federation of Labor, are Chairman and Vice-Chairman respectively of the 35 member Board of Directors.

The sponsoring agencies requesting the conference include the American Public Health Association and the National Health Council. The Technical Advisory Committee includes 52 leaders in health, education, social welfare, economics, and science, under the leadership of the program coördinator, Dr. Ernest G. Osborne of Columbia University.

The conference program is divided into three parts: Background Materials, which is largely statistical; Dynamics of Family Interaction; and Action Areas for Families and Organizations. The Chairman of the first section is Alexander Radomski who is the Assistant Program Coördinator of the National Conference on Family Life; of the second section, co-chairmen are Evelyn M. Duvall, Secretary of the National Council on Family Relations and

Reuben Hill, Professor of Sociology at Iowa State College. The third section, Health and Medical Care, is divided into 10 subsections, and is under the joint chairmanship of Haven Emerson, M.D., and Leona Baumgartner, M.D.; Coleman Woodbury of the University of Wisconsin heads the Housing Section.

The purpose of the Conference is to find specific ways in which Americans may work together to build their lives around a family core. It will deal with the importance of family living to democracy, the implications of housing, nutrition, child care, etc., for family stability, defining basic principles to help families understand and meet their needs in individual and group living, planning community resources including education for strengthening of families, and training professional workers in the field of family life.

The Conference is limited to 1,000 persons representing the 120 sponsoring agencies. The Secretary is Mrs. Clarice H. L. Pennock, and the national headquarters are at 10 East 40th Street, New York 16.

NATIONAL NUTRITION RESEARCH CENTER

The Medical School of Northwestern University has received from the Spies Committee for Clinical Research a grant of \$150,000 annually for 5 years to establish a national center for medical research in the field of nutrition at the University. Tom D. Spies, M.D., known for his work with synthetic folic acid, has been named Chairman of the new department and Professor of Nutrition and Metabolism.

Dr. Spies has been most recently Associate Professor of Medicine at the University of Cincinnati where, under the Spies Committee, he directed the University studies in nutrition in the Cincinnati General Hospital and in

the Hillman Hospital, Birmingham, Ala., which he organized in 1937. In his new capacity, he will continue to direct studies in Hillman Hospital.

ARKANSAS PUBLIC HEALTH ASSOCIATION

At a meeting in Little Rock in November, the organization of the Arkansas Public Health Association was completed. A Constitution and By-Laws were adopted, approximately 300 charter members enrolled and the following officers elected:

President—Edgar J. Easley, M.D., Director, Division of Venereal Disease Control, State Department of Health

Vice-President—Mrs. W. T. Dorrough, Executive Secretary, Arkansas Tuberculosis Association

Secretary-Treasurer—Roy M. Reid, Director of the Division of Public Health Education, State Department of Health

CINCINNATI PUBLIC HEALTH FEDERATION AWARDS

At the annual meeting of the Cincinnati Public Health Federation in December, awards of honor for distinguished service were made to William H. Muhlberg, M.D., and Bleeker Marquette. The awards consisted of a scroll, together with an engraved gold key, as tokens of the community's appreciation and gratitude.

Dr. Muhlberg is President of the Cincinnati Board of Health, of the Federation, and of the Anti-Tuberculosis League, and serves on many other community agency boards and was cited as "a staunch promoter and supporter of improvements in community organization and facilities for greater health protection and better medical care."

Mr. Marquette has since 1921 been Executive Secretary of the Public Health Federation and is also Executive Secretary of the Better Housing League and the Anti-Tuberculosis League. His citation reads in part: "Leader in the planning, organization, and development

of Greater Cincinnati's coordinated public health program."

DR. BUSTAMANTE, SECRETARY GENERAL, PAN AMERICAN SANITARY BUREAU

Miguel E. Bustamante, M.D., Dr.P.H., has been appointed Secretary General of the Pan American Sanitary Bureau. Immediately before going to Washington, D. C., he was Director of the Institute of Health and Tropical Diseases and Research Epidemiologist of Mexico, and Professor of Preventive Medicine and Hygiene in the School of Medicine.

Dr. Bustamante received his Medical degree from the National University of Mexico and his Doctor of Public Health degree from Johns Hopkins University.

In recent years, with Drs. Gerardo Varela, Ortiz Mariotte and Roch, Dr. Bustamante reported for the first time in a series of articles the presence in Mexico of Rocky Mountain spotted fever, its regional epidemiology and its transmission in the west and north central zones by the *R. sanguineus*, the characteristics of two strains and those of a fourth rickettsial entity found in the Michoacan State.

INDIANA'S NEW DEPARTMENT OF HEALTH BUILDING

Construction has begun on the new \$1,800,000 building for the Indiana State Department of Health. Located on the Indiana University Medical Center campus, it will be completed in January, 1949, and will have twice the space of the present building.

When the new building is completed, the old building will be deeded to the Medical Center for use as administrative offices and clinical laboratories.

THE THREADS OF RESEARCH IN CHILD LIFE

In November, 1947, the U. S. Children's Bureau called together 16 leaders in research in child life for a two day

conference in New York. Through group discussions, the conference considered what research in child life is now going on, in and out of the federal government; on what aspects of child growth and development and of community life in relation to children is research most needed; what the major obstacles to research are; what next steps should be taken; and what contributions the Children's Bureau can make.

In order to answer queries about the conference, the Children's Bureau has summarized some of the highlights. This includes a listing of 136 research projects currently being carried on in agencies outside the government as well as a list of Children's Bureau studies since 1912. This summary of the conference is available from the U. S. Children's Bureau, Washington 25, D. C.

POSTGRADUATE COURSE IN INDUSTRIAL MEDICINE

The Long Island College of Medicine announces its fifth Postgraduate Course in Industrial Medicine. Scheduled for the two week period, April 5-16, it is intended to provide physicians already in industrial practice or those planning to enter it, with information about the most recent developments in the field.

The courses will be given by 60 leaders in industrial medicine, authorities in allied fields, and members of the Medical School faculty. Tuition for the course is \$75. Address inquiries to Thomas D. Dublin, M.D., Department of Preventive Medicine and Community Health, 248 Baltic St., Brooklyn 2, N. Y.

ADVERTISING COUNCIL'S CHEST X-RAY CAMPAIGN

An earlier issue of the *Journal* (May, 1947, p. 635) reported preliminary plans for an educational campaign directed toward chest x-raying the entire adult population by the Advertising

Council in coöperation with the National Tuberculosis Association and the U. S. Public Health Service.

This campaign has now gone into its first major phase. The first network allocations were given the chest x-ray campaign during the week of January 12 and are being continued on an average of one week each month. Campaign guides, posters, car cards, and other materials have been prepared and sent out. Full information has been sent to all local tuberculosis associations and official health departments. The *NTA Bulletin* for January, 1947, gives details of the campaign as well as a description of the Advertising Council and its activities.

MR. SOLOW TO PAN AMERICAN UNION

In January, Anatole A. Solow began his new work as Housing and City Planning Specialist with the Division of Labor and Social Information of the Pan American Union in Washington, D. C. He will direct the Union's Housing and City Planning Information Service with particular reference to the official agencies and technicians of the Latin American countries.

Previously Mr. Solow was, since 1946, Research Associate of the Committee on the Hygiene of Housing of the American Public Health Association.

ATOMIC ENERGY EXHIBIT

The Brookhaven National Laboratory of the U. S. Atomic Energy Commission is holding a comprehensive exhibit on atomic energy from January 21 to April 5. Held in the American Museum of Natural History in New York City, it is intended to acquaint the public with some of the basic principles of atomic fission, the beneficial applications of nuclear energy, and the United States program in nuclear research and development.

Special group tours of the exhibit may also be arranged through the museum.

NATIONAL COMMITTEE ON LOCAL HEALTH UNITS

Recent issues of the *Journal* (Nov., p. 1502; Jan., p. 108) have reported on the Princeton Conference on Local Health Units and some of the activities flowing out of it. A meeting in New York in January brought further along plans for citizen participation.

After the Princeton Conference, the National Health Council, because of its special interest in this field, was asked to accept leadership in citizen participation in this program. It therefore called the January meeting in order that the agencies themselves might plan next steps. Forty-five of the national agencies represented at Princeton had representation at the January meeting. Among the outstanding features of the meeting was an agency by agency report on activities carried out since the Princeton Conference.

In addition to the items already reported in the January *Journal*, the National Congress of Parents and Teachers held a Health Conference on February 16 and 17 at which all their state health chairmen were briefed on ways by which they might forward the federal legislation sponsored by the National Congress as well as the community organization for extending minimum coverage or increasing the adequacy of present coverage.

Many of the agencies such as the Lions' Club, the American Home Economics Association, and the American Farm Bureau Federation have urged their local branches to study the results of the Princeton Conference in relation to their own community health needs.

Reports were made of articles to appear in various of the national agency journals as well as of plans to keep this matter constantly before state and local groups with appropriate educational material.

At the luncheon of the January meet-

ing Dr. Herman E. Hilleboe, New York State Health Commissioner, outlined briefly the plans for extending county health departments in the state. That the attitude of the local citizenry is the key to early and permanent progress was perhaps his outstanding point. He said that the help of citizens' groups was welcome and essential.

The conference discussed ways of carrying on the enthusiasm developed and furnishing the local agencies interested in the problem with suitable material. A number of regional conferences, for example, were suggested. The conference adopted ten resolutions as shown below and proceeded with the creation of a national committee in accordance with the mandate of Resolution Number 5. This committee is made up of the designated official representatives of each of the agencies that is interesting itself in this problem.

Resolutions Passed by the January 23 Conference

1. That each organization represented at Princeton be urged to approve officially, where possible, the principles of the Princeton resolution as soon as practicable and announce action with appropriate national publicity.

2. That the goal is to obtain complete coverage of all states and all communities by local full-time health units under competent professional direction.

3. That each organization be encouraged to develop a specific program of action adapted to its structure and character.

4. That to assure most effective results in obtaining complete coverage by full-time health units, it is essential that the activities of national agencies, although independent, at the same time be coördinated.

5. That the representatives of the organizations here gathered urge that the National Health Council, representing as it does the common interests of national agencies concerned with public health, be requested to create a National Advisory Committee on Local Health Units, composed of responsible representatives of interested organizations, such as those represented here and at the Princeton Conference, and such other organizations as may be determined subsequently.

6. That this committee, with the coopera-

tion of the above organizations, seek to develop a central program advisory service, materials and such other clearing house functions as may prove desirable.

7. That representatives at this meeting, in their individual capacities, recognize the necessity for federal assistance to states to complete the coverage of their respective populations and areas with full-time local health units under professional direction.

8. That the representatives at the meeting trust that the National Congress of Parents and Teachers will take primary responsibility for following through with the legislation proposed by the Association of State and Territorial Health Officers, and that such other organizations as were represented at the Princeton Conference, and which may so desire, will take action jointly with the National Congress of Parents and Teachers to support this legislation in principle.

9. That the national organizations be encouraged to begin stimulation of state and local action to obtain the necessary local health units. To this end, it is also suggested that appropriate graphically illustrated educational material be prepared nationally for distribution through local units of national organizations.

10. That each organization urge its state and local affiliates to work cooperatively with existing state-wide and local cooperating agencies or councils in order that there may be a pooling of interests, planning and action in securing the coverage referred to in recommendation 2. From this joint planning permanent organization for coordinated planning may be developed in those places where such does not now exist.

NATIONAL NEGRO HEALTH WEEK

National Negro Health Week will be observed from April 4 to April 11. Its special objective for the current year is: "A Practical Health Program for Myself and My Family: Learn what you ought to know—Health Education; Do what you ought to do—Healthful Living."

The preliminary announcement sent out by the Committee lists a community organization plan and a day by day schedule for Health Week, as well as some 60 suggested sources of cooperation.

For further information, write Na-

tional Negro Health Week Committee, U. S. Public Health Service, Washington 25, D. C.

ANNUAL PARENTS' MAGAZINE MEDAL TO DR. ELIOT

The 1948 *Parents' Magazine* Medal for Outstanding Service to Children was presented in January to Martha M. Eliot, M.D., President of the Association and Associate Chief of the U. S. Children's Bureau in Washington.

In presenting the medal the speakers, George J. Hecht, publisher of *Parents' Magazine*, and Senator Saltonstall of Massachusetts, praised her work as Director of the Emergency Maternity and Infant Care Program and as Chief Medical Consultant of the International Children's Fund. Said Senator Saltonstall: "Dr. Eliot truly has become a leading authority on child care. You can almost say that whenever child health is mentioned, Dr. Eliot's name comes first in your mind."

INSTITUTE OF EXPERIMENTAL BIOLOGY AND MEDICINE

The U. S. Public Health Service has established an Institute of Experimental Biology and Medicine in the National Institute of Health in Washington. This research institute, combining the functions of the Division of Physiology and of the Pathology and Chemistry Laboratories, is designed to achieve greater coordination of scientific investigations.

William Henry Sebrell, Jr., M.D., Chief of the Division of Physiology, is the Director of the new Institute, serving also as Associate Director of the National Institute of Health.

Dr. Sebrell, an authority in the field of nutrition, has been with the Public Health Service since 1925. In 1940, he received the Mead Johnson Award of the American Institute of Nutrition for research on vitamin B-complex, and in 1946, was awarded the research medal of the Southern Medical Association.

In 1945, he spent 3 months in Europe as nutrition consultant to the U. S. Army's Military Government Public Health Staff, for which he was awarded the Legion of Merit.

PROFESSIONAL RESPONSIBILITIES

The following extract from an article appearing in the December 1, 1947, issue of *The Connecticut Technical Council, Inc.*, gives in compact form the *raison d'être* for the engineering professional societies.

OUR SOCIETIES

PROFESSIONAL RESPONSIBILITIES AND PURPOSES

All engineering societies have been brought into being by ideals for advancement, for improvement or for public service. An examination of these ideals as stated in purposes of various societies reveals a pattern of professional responsibility in six primary categories:

First Responsibility. To extend and advance engineering knowledge and art; to encourage original research to promote standardization of engineering specifications and methods of testing; to maintain a library; to confer honors and awards for outstanding work.

Second Responsibility. To maintain high aims and standards for the education of those who are to become engineers; to foster engineering education; to foster among engineering students the study of philosophy and history, traditions and achievements, duties and social functions of the engineering profession; to encourage the personal and professional development of young engineers.

Third Responsibility. To maintain high standards for entrance into the profession; to aid in adoption of a high standard of attainment for granting the legal right to practice engineering; to maintain high cultural and technical standards for admission to the society.

Fourth Responsibility. To increase the usefulness of the engineering profession; to cooperate with other engineering and technical societies; to advance the unity of the profession; to secure greater public understanding of the purposes of the profession; to secure equitable compensation for engineering services.

Fifth Responsibility. To maintain high standards of conduct between the engineer and his client, his employer, his colleagues, and the public; to maintain high professional standing; to protect the public against unqualified engineering practice.

Sixth responsibility. To minister to the public interest; to encourage a high standard

of citizenship among engineers; to encourage engineers to participate in public affairs; to cooperate with governmental agencies on engineering matters; to cooperate internationally on engineering matters.

The above principles were prepared after an analysis of the stated purposes of the various professional engineering societies.

DR. OSBORN IN CONNECTICUT 25 YEARS

In December, the Public Health Council of Connecticut and the staff of the State Health Department, celebrated the completion of a quarter of a century of service by the State Health Commissioner, Stanley H. Osborn, M.D. Dr. Osborn was presented with a traveling bag in appreciation of his many years of service. When he first became Commissioner in 1922, the department's staff numbered 50; expanded services have increased the staff to a current 300.

In point of service, Dr. Osborn is the second oldest State Commissioner of Health in the country. A. J. Chesley, M.D., of Minnesota, has served one year longer, having been appointed Secretary and Executive Officer of the Minnesota State Board of Health in 1921.

FIELD TRAINING PROGRAMS

The recent *Bulletin of Field Training Programs* lists the various programs of training available through the Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga., for the year 1948. Field training for sanitary engineers, sanitarians — general and milk and food, insect and rodent control personnel and various laboratory workers are included. Most of the programs are given at the Center in Atlanta, Ga., although other centers in Savannah, Ga., Topeka, Kans., Troy, N. Y., Columbus, Ga., and Cincinnati, Ohio, are included. As in the past, tuition is free but no stipends are available from the Communicable Disease Center for traveling or living expenses during the course of study. R. A. Vonderlehr

is Medical Director in Charge, and E. S. Tisdale is Chief, Training Division of the Communicable Disease Center.

INDIANA'S FIRST BI-COUNTY HEALTH DEPARTMENT

The Boards of Commissioners of Floyd and Harrison Counties in Indiana with a combined 1940 population of 52,000, passed appropriations for setting up immediately a bi-county public health department. Its full-time medical Health Officer is W. E. Amy, M.D., formerly a practising physician.

Headquarters will be in New Albany. Currently, the staff will include two sanitarians and five nurses with two additional nurses planned for a later date.

A LOUISIANA CITY AND COUNTY CONSOLIDATE THEIR GOVERNMENTS

By a recent vote, the city of Baton Rouge and the parish (county) of East Baton Rouge consolidated their respective governments with a council of nine members. Unified departments of public works, purchasing, finance, and personnel will furnish parish-wide services to a population of more than 100,000.

The health services of city and parish had already been unified before this action. Schools and recreation will not be under the control of the council, the former being governed by a popularly elected council of seven members and the latter by a board created by special legislative act.

FIRST APPROVED HOSPITAL CONSTRUCTION PROJECT TO COMBINE HOSPITAL AND HEALTH SERVICES

The first project to be approved under the 1946 hospital construction act (P.L. 725) is for a combined hospital and health unit in Langdale, Chambers County, Alabama. The project, sponsored by the Chattahoochee Valley Hospital Society in Langdale, was ap-

proved by the Surgeon General on November 5, 1947. Langdale is an industrial community (about 2,000 textile mill employees) located in a rural county with a 1940 population of 41,000.

The plans as approved include 82 hospital beds which can be increased to 150 if needed and preventive and public health services. The hospital building will house an outpatient clinic and the county public health department. Total construction cost is estimated at \$1,700,000. Dr. C. C. Applewhite, who furnished the above information, observes that, "It is a gratification to us that the first approved project in the country and in District (U. S. Public Health Service) No. 4, combines in one structure facilities for preventive medicine as well as for treatment and care of the ill."

FIRST TRI-COUNTY UNIT IN OHIO

Beginning in January, Ohio's first tri-county health unit began operation. It is a consolidation of two already existing units, Delaware City-County and the bi-county unit of Madison and Union. The total population being served is about 70,000.

The Health Officer of the new tri-county health department is Wayne S. Ramsey, M.D., who has been with the U. S. Public Health Service since January, 1944. Previously, he had seen service in both world wars, with the Pennsylvania State and Alaska Territorial Boards of Health and with the Michigan Crippled Children's Commission.

DEDICATION OF M.I.T. LABORATORIES

The Massachusetts Institute of Technology recently dedicated the William Thompson Sedgwick Laboratories of Sanitary Science of the Department of Civil and Sanitary Engineering, with Dr. John B. Wilbur, Head of the Department, presiding.

Speakers included Professor Samuel C. Prescott, Arthur D. Weston, and Dean Gordon M. Fair of the Harvard School of Engineering. Professor W. E. Stanley described the new facilities and the work they will do. Murray P. Horwood, Ph.D., is in charge of the Laboratory of Sanitary Bacteriology and Research; Clair N. Sawyer, Ph.D., of the Laboratory of Sanitary Chemistry; and Professor Ariel A. Thomas, of the Laboratory of Sanitary Engineering.

NATIONAL ASSOCIATION OF SANITARIANS

The following officers were elected for the year 1948 at the 11th Annual Meeting of the National Association of Sanitarians in Salt Lake City in September, 1947:

President—Mitchell P. Mondala, Washington State Health Department

Vice-President—C. W. Clark, Oregon State Health Department

Jr. Past-President—E. R. Shields, Utah State Health Department

Treasurer—Charles H. Ziegler, City Health Department, Los Angeles

Executive Secretary—Roscoe C. Davis, California State Health Department

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION APPOINTS EXECUTIVE SECRETARY

Elizabeth K. Caso has been appointed Executive Secretary of the Massachusetts Public Health Association. An instructor in nutrition in the Harvard School of Public Health, Mrs. Caso will serve the Public Health Association on a part-time basis. It is hoped that the employment of an Executive Secretary will increase the services the Association can render to its members, and make the agency a more potent influence for the improvement of public health administration in Massachusetts.

LIP READING SCHOLARSHIP

The Kenfield Memorial Fund, through the American Hearing Society,

is offering a scholarship of \$100 to a prospective hard of hearing teacher of lip reading who lives in the United States.

Applicants must have: personal characteristics necessary for successful teaching; ability to read lips and professional training in lip reading; a bachelor's degree or its equivalent. The prospective teacher who wins the scholarship may take the normal course from any normal training teacher or school or university in the United States offering a course acceptable to the Teachers' Committee of the American Hearing Society.

Applications must be filed between March 1 and May 1, 1948, with Miss Rose V. Feilbach, 2431-14th Street, N.W., Washington 9, D. C.

AMENDMENTS TO NEW YORK STATE SWIMMING POOL REGULATIONS

The December 15, 1947, issue of New York State *Health News* includes as a supplement an amendment to the *State Sanitary Code* covering swimming pools and bathing beaches. In preparing the material for the amendment the suggested revision of the Code was sent to several municipal and county health departments for criticism.

In addition to clarifying the previous section of the *State Sanitary Code* dealing with swimming pools and bathing beaches some subjects have been added and others expanded. Requirements on dressing and toilet rooms now require adequate shower bath facilities at artificial swimming pools where the source of bacterial pollution is the bathers themselves. The maximum number of bathers permitted to use such a pool is now based on the surface area of the pool rather than on water volume. Filtration must be provided at artificial pools when required by the local health officer or the State Commissioner of Health. Regulations covering the sanitary

quality of water and the techniques used in chlorination have been modernized, and measures for the safe handling of chlorine gas have been added. Requirements on bacterial quality of water at partly artificial swimming pools or at bathing beaches have not been specified because numerical bacterial standards for this purpose are not available. The local health officer or the State Commissioner of Health is given authority to prohibit bathing where a menace to the health of bathers is believed to exist.

NSPB MOVES TOWARD COMMUNITY COÖPERATION

At the December meeting of the Board of Directors of the National Society for the Prevention of Blindness, the following resolution prepared by the Society's Committee on Plan and Scope was approved:

It is the stated policy of the National Society for the Prevention of Blindness to participate in joint planning and coöperative action with other educational, health, and social agencies, both voluntary and official. It is recommended, therefore, that state, territorial, city and county prevention of blindness associations likewise coöperate with appropriate agencies in educational programs, planning for community health and welfare, and other activities.

NEW OFFICERS OF FLORIDA PUBLIC HEALTH ASSOCIATION

At its Annual Meeting held in Tampa, October 23-25, 1947, the Florida Public Health Association elected the following new officers to serve for 1948:

President—Wilson T. Sowder, M.D., Jacksonville
1st Vice President—Russell Broughman, Miami
2nd Vice President—Martha Stetson, St. Petersburg
Secretary—Fred B. Ragland, Jacksonville
Treasurer—Elsie Hyatt, Jacksonville

DR. SELLERS, GEORGIA HEALTH COMMISSIONER

In December, Thomas A. Sellers,

M.D., was appointed Georgia Health Commissioner by the State Board of Health, following the retirement of T. F. Abercrombie, M.D., who has been Commissioner since 1917. Dr. Sellers has been in the State Health Department more than a quarter of a century, during nearly all of that time as Director of Laboratories.

Dr. Abercrombie remains in the department as Director Emeritus and in an advisory capacity.

At the same Board meeting, John E. Ransom was made Director of the newly created Division of Hospital Construction. He has been serving in the department as hospital consultant, having formerly been Director of the Hospital Council of New York.

OREGON'S NEW DISTRICT HEALTH UNIT

Lincoln and Tillamook Counties, with a 1940 combined population of 27,000, have formed a district health unit under the law enacted by the 1947 Oregon legislature. The position of health officer had not been filled in December and the unit was operating with the temporary services of a part-time health officer.

Two other counties that had been operating on a coöperative basis—Washington and Yamhill—with 65,000 population, have also organized under the new law. Three other coöperative units including 7 counties are also expected to organize formally under the new law.

INTER-AMERICAN SANITARY ENGINEERING CONGRESS

The first Inter-American Sanitary Engineering Congress will be held in the University of Chile, Santiago, April 8-14. Joining with the Inter-American Association of Sanitary Engineering in sponsoring the Congress are the Chilean Ministries of Public Health and of Public Works, the Santiago Department of Water and Sewerage, the Pan American Sanitary Bureau, and the Institute of Inter-American Affairs.

Further information may be secured from Donald L. Snow, Acting Secretary, Inter-American Association of Sanitary Engineering, 2001 Connecticut Ave., N.W., Washington 8, D. C. Details on the United States manufacturers' exhibits are being handled by Arthur T. Clark, Water and Sewage Works Manufacturers Association, 170 Broadway, New York 7.

DR. SCHEELE APPOINTED SURGEON
GENERAL, U. S. PUBLIC HEALTH
SERVICE

It was announced at the White House on February 12 that Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service since 1936, would be succeeded at the expiration of his term on April 6, 1948, by Leonard A. Scheele, M.D., now an Assistant Surgeon General of the U. S. Public Health Service and Head of the National Cancer Institute, Bethesda, Md.

Dr. Parran, who is completing his third term of 4 years as Surgeon General, was appointed to the post in April, 1936, by President Roosevelt. According to the report, Dr. Parran will resume his permanent status in the Service as Medical Director and has announced that he has no further plans after his retirement as Surgeon General.

Dr. Parran stated that the President was to be congratulated upon his appointment of Dr. Scheele who he said was "one of the outstanding figures in public health in the United States, possessing both the professional and personal qualifications to be a great Surgeon General. I wish for him long years of useful public service in this responsible position."

During Dr. Parran's 12 years as Surgeon General, many new programs have been developed by the Service, including Venereal Disease and Tuberculosis Control Programs, the National Mental Health Program, the National Cancer

Program, the National Hospital Survey and Construction Program and, during the war period, the Cadet Nurse Corps. In addition, an expansion of the National Health Institute and the Grants-in-Aid Programs were accomplished. Budgets of the Public Health Service during this period increased from less than 15 million to more than 100 million dollars a year.

Dr. Scheele, who is a native of Indiana, was born July 25, 1907 and is a graduate, in 1934, of the Wayne University School of Medicine, Detroit. He has been a member of the Regular Corps of the Public Health Service since July 10, 1934, and was on a European assignment with the Army during the war after service with the Office of Civilian Defense.

OFFICERS OF AMERICAN HOSPITAL
ASSOCIATION

The following officers of the American Hospital Association were elected at its annual meeting in St. Louis:

President—Graham L. Davis, Director, Division of Hospitals, W. K. Kellogg Foundation

President-Elect—Joseph G. Norby, Superintendent, Columbia Hospital, Milwaukee

First Vice President—M. H. Eichenlaub, Superintendent, Western Pennsylvania Hospital, Pittsburgh

Second Vice President—Ruth C. Wilson, Executive Director, Martine Hospital Service Association, Moncton, New Brunswick

Third Vice President—F. Ross Porter, Administrative Assistant, Duke Hospital, Durham

The officers reported on page 1639 of the December issue of this *Journal* should have been identified as officers of the American College of Hospital Administrators.

NEW OFFICERS OF THE SOCIEDADE
BRASILEIRA DE HIGIENE

At the annual election of officers of the Sociedade Brasileira de Higiene held on December 22, 1947, Dr. Mar-

colino Gomes-Gandau was elected *President* of the Society and Dr. Geraldo Paula Souza *Vice-President*.

PERSONALS

Central States

VIOLET DuBois,† has been appointed Health Educator of the Omaha City-Douglas County Health Department in Nebraska where she will also be on the teaching staff of Omaha University. Miss DuBois was formerly Assistant Director of Health Education, Nebraska State Health Department.

PAUL FUGAZZOTTO, Ph.D.,† has been appointed serologist in the Bureau of Laboratories, Indiana State Health Department. He was formerly with the Michigan State Health Laboratories, first in the Grand Rapids Laboratory working with PEARL KENDRICK, M.D.,* in her pertussis studies, and later at the Central Laboratory in Lansing.

FRED L. MAYES, M.D.,* has been appointed Health Officer of Wichita, Kan., effective June, 1948. Dr. Mayes has been Assistant State Health Officer of Kansas and Director of the Division of Local Health Administration, and is currently on leave studying for a Master's Degree in public health at the Harvard School of Public Health.

THURMAN B. RICE, M.D.,† who for some years has been Chairman of the Department of Bacteriology and Public Health, University of Indiana School of Medicine, has now been named Chairman of the new Department of Public Health.

Eastern States

FRANKLYN B. AMOS, M.D.,* has been appointed Director of the new Office of Professional Recruitment and Training of the New York State

Health Department. Dr. Amos has been with the department since 1935, as Assistant Director of local health administration since 1940.

WILLIAM A. BRUMFIELD, M.D.,* has been appointed Deputy Commissioner of Health of New York State succeeding JAMES E. PERKINS, M.D.,* who resigned to become Managing Director of the National Tuberculosis Association. Dr. Brumfield has been Director of the Division of Venereal Disease Control of the Department for the past 12 years.

JAMES P. DIXON, M.D.,† Philadelphia, Pa., became Director of Denver General Hospital on October 1. He has been administrative intern under LUCIUS R. WILSON, M.D., at the Episcopal Hospital in Philadelphia, and is a former fellow in public administration and hospital administration at the W. K. Kellogg and Rockefeller Foundations.

JAMES A. DOLCE, M.D., M.P.H.,* Chief of Division of the Local Health Administration, Connecticut State Health Department since July 1, 1945, has been appointed Deputy Commissioner of the Buffalo City-Erie County, New York Department of Health.

LYMAN C. DURYEA, M.D., M.P.H.,* who served for the past year as Medical Director of the Research Council on the Problems of Alcohol, New York, N. Y., has resigned to accept a commission with the U. S. Army. He has been assigned as Commanding Officer of the 269th General Hospital, Fitzsimmons General Hospital, Denver, Colo. JOSEPH HIRSH,* Associate Director of the Council, is serving as Acting Director.

CARL L. ERHARDT,† Assistant Director of the Bureau of Vital Statistics,

* Member A.P.H.A.

† Fellow, A.P.H.A.

Connecticut State Health Department since April 15, 1947, will return to the New York City Health Department as Director of the Bureau of Records and Statistics. Mr. Erhardt had previously been associated with the New York Bureau for 11 years.

STEPHANIE F. FORD,† on January 5 assumed the position of School Health Educator of the New York Tuberculosis and Health Association. Miss Ford was formerly with the public school system of Hamden, Conn.

PAUL R. GERHARDT, M.D.,† has been appointed Director of New York State Health Department's new Division of Cancer Control, effective in January. He succeeds MORTON L. LEVIN, M.D.,* who was named Assistant Commissioner for Medical Administration last October. Dr. Gerhardt comes to the Department from the West Virginia State Health Department where he has been Director of the Division of Cancer Control since April, 1944.

GERMAINE A. GUNTZER, M.D.,† has been appointed to the medical staff of Leahi Hospital, the 900 bed tuberculosis sanatorium at Honolulu, Hawaii. He has most recently been Medical Consultant for Veterans of the National Tuberculosis Association in New York.

CHARLES HAYDOCK,† Consulting Engineer, Philadelphia, Pa., has been appointed by GOVERNOR JAMES H. DUFF as a member of the Pennsylvania State Registration Board for Professional Engineers.

H. R. KILANDER, Ph.D.,† has resigned as Associate in Health Education of the National Tuberculosis Association, New York, N. Y., to become Associate in Health Education of the U. S. Office of Education, Washington, D. C.

DOMINICK J. LACOVARA, M.D., Ph.D.,† formerly resident psychiatrist at Mat-

teawan State Hospital, Beacon, N. Y., late in September, 1947, became resident psychiatrist of Craig House, Beacon, N. Y., a private sanitarium, and was appointed consulting psychologist to Matteawan State Hospital.

EUGENE L. LEHR, C.E.,† Housing Engineer with the Bureau of Sanitary Engineering, Connecticut State Health Department since August, 1938, has taken up his duties as town engineer and Superintendent of Public Works, Fairfield, Conn. This is a position created by the new charter adopted at the 1947 Session of the Connecticut General Assembly.

JOHN J. LENTZ, JR.,† who, since he left the Army and served with the Division of Medical Sciences of the National Research Council in Washington, D. C., has now joined the staff of Young and Rubicam, New York, N. Y., to be concerned with research for health and medical advertising.

CHARLES McCLAIN, who has been rehabilitation consultant of the National Tuberculosis Association, New York City, since 1944, has been named Director of the new rehabilitation department of Mont Alto Sanatorium in Pennsylvania.

JOHN F. McCORMACK, former Superintendent of Presbyterian Hospital, New York, N. Y., has been appointed Executive Vice-President of United Medical Service in New York City.

CHARLES L. NEWCOMB, Director of the Christmas Seal Sale of the National Tuberculosis Association for 18 years, retired December 31, 1947. Miss Frances Brophy, Associate, Seal Sale Service, has been appointed Acting Director.

CLELAND A. SARGENT, M.D.,† has been appointed Health Commissioner of Syracuse, N. Y., effective June 1, 1948, when the present Commissioner, H. BURTON DOUST,

M.D.,† retires. Dr. Sargent is at present a District Health Officer of the New York State Department of Health.

RALPH SIKES, M.D.,* former Health Commissioner of Norwalk, Conn., is Health Commissioner of Yonkers, N. Y., succeeding BERWYN MATTISON, M.D.,† who recently became Buffalo City-Erie County Health Commissioner.

NORMAN SURVIS, M.D., New Rochelle, N. Y., has been appointed Director of the Division of Pediatrics of the Westchester County Health District, White Plains, N. Y., succeeding DOROTHY WORTHINGTON, M.D.,* resigned.

MARGARET WOLCOTT, R.N., M.P.H.,† has been appointed Director of Nurses of the Cortland County (N. Y.) Health Department. Since 1931, Miss Wolcott has been with the New York State Department of Health, having been assigned to the Cortland County Health Department as Supervising Nurse in 1943.

Southern States

CHANGES IN FLORIDA HEALTH PERSONNEL:

JOHN ROSS HAGUE, M.D.,† formerly of Washington, D. C., has been appointed Health Officer of the Indian River, St. Lucie and Okeeshobee Counties Health Unit, with headquarters at Fort Pierce.

M. LEWIS GRAY, M.D., formerly Health Officer of the Jackson and Washington Counties Health Unit is now Health Officer of the Broward County Health Department with headquarters at Fort Lauderdale. He succeeds WILLIAM C. HATCHETT, M.D., who resigned due to ill health.

ROBERT H. HEAD, M.D., has been

appointed Health Officer of the Jackson and Washington County Health Departments, with headquarters at Marianna.

CHARLES G. CHAPLIN, M.D., has been appointed Health Officer of the Jefferson County Health Department with headquarters at Monticello. Formerly on the staff of Englewood Hospital, Chicago, Ill., he succeeds B. L. ARMS, M.D., who is retiring.

WILLIAM G. C. HILL, M.D., Director of the Putnam and Flagler County Health Departments has resigned his position.

FRANCIS M. COY, M.D., succeeded HARRY W. HOLLINGSWORTH, M.D., on February 2 as Director of the Highlands, Glades, and Hendry County Health Units.

CARL J. HEISSER,† has resigned his position as Medical Statistician in the Medical Statistics Division, Bureau of Medicine and Surgery, Navy Department, Washington, D. C., to accept the position of Superintendent and Registrar of the Bureau of Vital Statistics of the Toledo, Ohio, Department of Health.

MARK DEXTER HOLLIS,† recently Executive Officer in the Office of the Surgeon General, has been appointed Chief of the Sanitary Engineering Division of the U. S. Public Health Service, with the rank of Assistant Surgeon General. He was formerly Director of the Service's Communicable Disease Center in Atlanta where he developed a program for malaria and typhus control.

CLARKE W. MANGUN, JR., M.D.,† is the new Director of Tuberculosis Control Division of the Kentucky State Department of Health. Formerly in the same position in the Florida State Department of Health, he has most recently attended the Columbia University School of Public Health, New York, N. Y., where he received

* Member A.P.H.A.

† Fellow, A.P.H.A.

his Master of Public Health degree in June, 1947.

GRADIE R. ROWNTREE, M.D.,* Deputy Director of Public Health, Louisville-Jefferson County, Kentucky Health Department, resigned on January 1 to become Medical Director of the C. T. Dearing Printing Company. WILLIAM F. LAMB, M.D., M.P.H.,† formerly Assistant Director in charge of communicable diseases succeeded him as Deputy Director of the Health Department.

AGNES SCHULZ became nutrition consultant for the Oklahoma State Department of Health, on January 1, 1948. She succeeds MAURINE MEIER LEIGHTON, resigned.

CHARLES A. SMITH, M.D., was named Director of the Mental Hygiene Division, Oklahoma State Department of Health, on December 1. Dr. Smith is now Assistant Professor of Psychiatry and Neurology of the University of Oklahoma School of Medicine.

MARTHA PETTIT VAN METER,† became Acting Director of the Division of Public Health Education of the Kentucky State Health Department in October, 1947.

Western States

HERBERT BAUER, M.D.,† has resigned as San Luis Obispo County Physician for a year's study in public health on a fellowship granted by the National Institute of Health, Washington, D. C. Dr. Bauer will study at the School of Public Health, University of California.

MARTIN D. BAUM, D.V.M., M.P.H.,† formerly City Veterinarian and Director, Division of Milk and Meat Inspection, City Health Department, Los Angeles, Calif., has been appointed Public Health Veterinarian, U. S. Public Health Service, assigned to Colorado State Department of Public Health, Denver, Colo.

HELEN HORKAVI,† was appointed Tuberculosis Nursing Consultant of the Arizona State Department of Health beginning December 1, 1947. She has served in the Pima County Health Department in Tucson, Ariz., and for the past 3 years as Director of Public Health Nursing, Marquette University, Milwaukee, Wis.

ROLAND H. LODER, M.D., M.P.H.,* became the Health Officer of Weld County, Colorado, effective January 1. For 10 years previously, he had been Director of Maternal and Child Health of the Nebraska State Health Department.

CLARA WOLFE, R.N., will serve as Educational Director for the Veterans' Administration in Oregon having resigned as consultant nurse for the Oklahoma State Department of Health.

Other Areas

L. W. FITZMAURICE, M.D.,* Director of Medical Services, Kingston, Jamaica, has recently been elected a Fellow of the Royal Sanitary Institute of London, England.

SÉRVULO LIMA, M.D.,† has resigned from the Serviço Especial de Saude Publica, Rio de Janeiro, Brazil, and MARCOLINA GOMES-CANAU, M.D.,† has succeeded him as Superintendent.

NAIL P. MACPHAIL, M.D., received the 1948 Richard P. Strong Medal for outstanding service in tropical medicine at the annual dinner of the American Foundation for Tropical Medicine in New York on January 8. Dr. MacPhail is surgeon and sanitarian of the United Fruit Company, stationed in Quirigua, Guatemala.

F. MALO-JUVERA, M.D., M.P.H.,† has been promoted from Chief of the Division for Training of Health Personnel to Technical Adviser to the Undersecretary, Ministry of Public Health and Welfare, Mexico, effective January 1.

The Health Officer's Bookshelf*

HUNTINGTON WILLIAMS, M.D., DR. P.H., F.A.P.H.A.

Commissioner of Health of Baltimore, Md.

Dr. Oliver Wendell Holmes cast a divine spell in writing "The Chambered Nautilus" and saved many thousands of lives by publishing his essay on "The Contagiousness of Puerperal Fever." The good doctor loved his medical library and the wisdom hidden away in some of its old-time folios. They gladdened his eye and he cuddled them. He bought them even beyond the verge of extravagance. "These books," he said, "were very dear to me . . . A twig from some one of my nerves ran to everyone of them."

NEARLY every health officer enjoys his work or he would not be a health officer. If he can feel as Oliver Wendell Holmes did about his books, so much the happier will he be; but it is not essential. His duties soon teach him that the health department needs certain books as daily desk-side tools. Experience may deepen the perspective so that the bookshelf at his hand expands to something to be cherished for being more than merely a tool kit.

No two public health workers will ever pick the same list of "must books." Heaven forbid. Life is a twenty-four hour proposition. There may well be three sections in the health officer's bookcase; one beside his desk in the office, one by a good reading lamp at home, and a small bedside shelf for half a dozen favorites.

So now to a consideration of some twenty or thirty or more books that the

large or even the small health department might wish to see upon its shelf.

1. *Rosenau, M. J. Preventive Medicine and Hygiene* (6th ed.), Appleton-Century, N. Y., 1935. A veritable encyclopedia that is trustworthy as a friend. It may be turned to for standard knowledge or to meet the emergency that keeps cropping up when a health officer is expected to provide his community with an official statement, and when he has never had to answer *that* question before. Indeed indispensable. And perhaps there may be a new edition.

2. *Papers of Charles V. Chapin, M.D.* The Commonwealth Fund, 41 East 57th St., N. Y. 22, 1934. An inexpensive gold mine which includes some of the best of the invaluable papers by the great Superintendent of Health of Providence, R. I., for the period 1884-1931. They deal with communicable disease control, epidemiology, and vital statistics, and made an immortal of the author, for single-handed he abolished the fetish of fumigation that goes back in history

* Special Review Article prepared at the request of the Editorial Board.

to Homer and the *Odyssey*. His earlier classic is *The Sources and Modes of Infection* (2nd ed.), Wiley, N. Y., 1912. Not unlike these writings of Chapin are the *Papers of Wade Hampton Frost, M.D.* The Commonwealth Fund, N. Y., 1941. Both Chapin and Frost are the intellectual heirs of John Snow whose volume on cholera (London, 1855) was republished by the Commonwealth Fund in 1936, and of William Budd whose *Typhoid Fever* (London, 1873) was reprinted by the Delta Omega Society and the American Public Health Association in 1931.

3. *The Control of Communicable Diseases* (6th ed.), 1945. An Official Report of the American Public Health Association. This 149 page pocket-size pamphlet is now recognized nationally and internationally as authoritative on the moot points of isolation and quarantine, sources and modes of infection, and control procedure. An inexpensive booklet (35 cents) that is turned to daily in a thousand health departments and provides the very best consensus of opinion.

4. *Anderson, Gaylord, and Arnstein, Margaret. Communicable Disease Control* (2nd ed.), Macmillan, N. Y., 1948. A very sound and up to the minute guide when a health officer or public health nurse is perplexed by such an every-summer-day question as "What can be done to prevent poliomyelitis?"

5. *Topley and Wilson's Principles of Bacteriology and Immunity*. Revised by G. S. Wilson and A. M. Miles (3rd ed.), two volumes. Williams & Wilkins, Baltimore, 1946. Considered by many health officers, laboratory workers, and communicable disease hospital administrators to outrank most other like volumes. From the London School of Hygiene and Tropical Medicine.

With Topley and Wilson's *Principles* may well be mentioned some recent writings by F. M. Burnet, M.D. of Melbourne, Australia, such as his *Bio-*

logical Aspects of Infectious Disease, Cambridge University Press (England), 1940. The struggle for existence between man and the microorganisms here discussed is to some extent reminiscent of the writing and the thinking of Charles V. Chapin and William H. Park.

6. *Top, Franklin H. Communicable Diseases (A Handbook)* (2nd ed.), Mosby, St. Louis, 1947. A good book with 95 text illustrations and 13 color plates.

7. *Winslow, C.-E. A. The Evolution and Significance of the Modern Public Health Campaign*. Yale University Press, 1923. In spite of the fact that this 65 page lecture is out of print, it is hoped temporarily, it is perhaps the best brief historical review of what the health officer's work is all about. The booklet is hard to put down until the reader finishes it. It is difficult to keep from referring to it, and its footnotes abound in references to other like publications of top rank.

Among them, *facile princeps*, is *English Sanitary Institutions* by Sir John Simon, London's first Medical Officer of Health, who was appointed just a century ago. This Simon volume (London, 1890 and 1897) is hard to come by, unless you learn the ways of the British booksellers and their catalogues. William H. Welch in his Sedgwick Memorial Lecture in 1924, *Public Health in Theory and Practice*, a historical review, says "Something of the story of the various influences, movements, and events which culminated in this great sanitary awakening is told by Winslow in his Yale address, but every student of public health should read again and again the complete story as told so fascinatingly and authoritatively by Sir John Simon in his *English Sanitary Institutions*." (Simon pronounced his name "sea móan," because of his French ancestry.)

In the Winslow lecture appears a pro-

cession of our great public health pioneers, Edwin Chadwick, William Budd, Lady Montagu and Jenner, John Howard, Lemuel Shattuck, Stephen Smith, the founder of the American Public Health Association; Pasteur, W. T. Sedgwick; Biggs, Park and Welch, C. V. Chapin, Trudeau, Lillian Wald, Clifford Beers and Sir Arthur Newsholme. Beware of this thin tome (if you can find a copy) unless you are ready to be further intrigued into the study of the history of public health! The greater part of this dramatic segment of human history can be found in the same author's later volume, *The Conquest of Epidemic Disease—A Chapter in the History of Ideas*, Princeton University Press, 1943. It closes with a bibliography of "References" that you will by-pass at your own peril.

Another Winslow book, *The Life of Hermann M. Biggs*, Lea and Febiger, Philadelphia, 1929, is the biography of America's prime health administrator-statesman. With Welch and others, Biggs brought bacteriology to the U. S. A. and his life tells the story of the modernization of public health on the basis of this new science.

8. *Mustard, Harry S. An Introduction to Public Health* (2nd ed.), Macmillan, N. Y., 1944. A valuable text for health officer, physician, public health nurse or layman, written by a master health officer now serving America's largest city in that capacity. The state or county health officer will wish to study another of Dr. Mustard's many publications; *Rural Health Practice*, The Commonwealth Fund, N. Y., 1941. This comes from first-hand experience for the author was formerly a county health officer.

9. *Hiscock, Ira V. Community Health Organization* (3rd ed.), The Commonwealth Fund, N. Y., 1939. A valuable time-tested summary of what is needed in any community in the way of public health service. Helpful for the health

department that wishes to check its current status; or for the board member, official or nonofficial, in the public health field. Will there be a fourth edition?

Among Dr. Hiscock's long list of helpful writings no health officer will wish to miss the volume he edited entitled *Ways to Community Health Education*, The Commonwealth Fund, N. Y., 1939. It is one of the best books of its kind, built out of the actual successful experience of some dozen or more health departments and agencies in teaching the public how to keep well. Fully illustrated and practical. Watch out for a re-issue or new edition, or both. Another good book on this subject may be mentioned here, *Health Education of the Public* by W. W. Bauer and T. G. Hull (2nd ed.), also well illustrated, Saunders, Philadelphia, 1942.

10. *Newsholme, Sir Arthur. Medicine and the State*. Williams & Wilkins, Baltimore, 1932. A truly remarkable volume. The author was long a local health officer in England and Chief Medical Officer of the (national) Local Government Board before the establishment of the British Ministry of Health in 1919. His career was crowned by broad international studies, practical thinking, teaching, and copious writing. The book is basic philosophy for present-day efforts in America to establish sound programs of medical care, social medicine or what you may prefer to call it. The insurance dollar comes down from above (protecting the well-to-do) to meet the tax dollar coming up from below (serving the relief client). When sound administration permits their junction the problem may be solved.

It seems that the American health officer, whether he likes it or not, is going to be drawn closer and closer to the administrative problems of medical care. There is growing up a vast literature on this general subject. A good recent volume by Franz Goldmann attempts to

give a composite picture of public medical care as a social movement. The title is *Public Medical Care—Principles and Problems*, Columbia University Press, N. Y., 1945. It closes with a valuable bibliography of "References."

As a health officer's interest broadens into these newer concepts of public health administration, he may wish to go back to the British Ministry of Health publication, sometimes called a modern "magna carta for public health," the *Interim Report on the Future Provision of Medical and Allied Services*, (Cmd. 693) May, 1920. He will find an American counterpart in the U. S. Public Health Service *Public Health Bulletin* No. 292 entitled *Health Service Areas: Requirements for General Hospitals and Health Centers*, Washington, 1945. He will wish to know of the *Report of the New York Academy of Medicine Committee on Medicine and the Changing Order*, The Commonwealth Fund, N. Y., 1947, and of other published studies of this committee that has since 1943 been investigating the subject of adequate medical care for the nation. And he may enjoy a fairly recent and challenging book on the practice of health in contrast with the practice of medicine as offered in a Family Club-Health Center combination in London just before World War II, namely, *The Peckham Experiment* by I. H. Pearce and L. H. Crocker, George Allen and Unwin, Ltd., London, 1943.

11. Smillie, Wilson G. *Public Health Administration in the United States* (3rd ed.), Macmillan, N. Y., 1947. A new edition, published in December, 1947. The frontispiece gives a vivid and thought-provoking statistical picture of "Our Aging Population" under which one reads "These changes in our population will require a complete reorientation of health and welfare activities." Apparently the health officer must wake up and stay awake.

Geriatrics, the "new word," appears

in the chapter on adult hygiene, where heart disease, cancer, diabetes and like problems are discussed briefly. Some of these matters recur in the chapter devoted to the voluntary health agencies, and reference is made in that chapter to the volume published in 1945 by S. M. Gunn and P. S. Platt entitled *Voluntary Health Agencies—An Interpretive Study*. Smillie's chapters on health administration in the federal government and on the national health program give a clear picture of the recent reorganizations under the Federal Security Agency and include references to the Hill-Burton hospital construction act, and the mental health act.

12. Tobey, James A. *Public Health Law* (3rd ed.), The Commonwealth Fund, N. Y., 1947. An old standby and friend to the health officer, serving a double purpose in the interpretation of law to the health officer, and of public health to the lawyer and the judge. The Foreword is by Charles V. Chapin, and there are chief sections on the public law and on administration, the powers and duties of health departments, and liability. Page-by-page pertinent court-case references appear in the footnotes.

13. *Physicians' Handbook on Birth and Death Registration*. U. S. Bureau of the Census (9th ed), 1943. This is a modest little gem of a 94 page government pamphlet. It contains the International List of Causes of Death with index and is perhaps the simplest and most helpful introduction to vital statistics that can be found. The selected bibliography will be difficult to resist and much of the appendix material will delight the health officer when he first sees it. It may well become his habit to place a copy in the hands of every physician who practises within his jurisdiction. (State and local health officers kindly omit duplication.) Copies are supplied gratis by the Bureau of the Census. Keep an eye out for the Sixth

Decennial Revision now in preparation for apparently there will be added an International List of Diseases as well as the standard List of Causes of Death.

14. *Gardner, Mary Sewall. Public Health Nursing* (3rd ed.), Macmillan, N. Y., 1936. The book is well known and valuable for its endeavor to serve as a general outline of public health nursing. Beside it on the shelf might stand *The Public Health Nurse and Her Patient* by Ruth Gilbert, published by The Commonwealth Fund, N. Y., 1940, where the author brings into the picture the important matters of mental hygiene and behavior. Another helpful volume in this field is the *Manual of Public Health Nursing* (3rd. ed.), Macmillan, N. Y., 1939, prepared by the National Organization for Public Health Nursing.

15. *Spock, Benjamin. The Pocket Book of Baby and Child Care*. Pocket Books, Inc., N. Y., 1946. An inexpensive (35 cents) authoritative common-sense guide for parents, integrating the physical and emotional aspects of child care.

Printed works on mental hygiene are innumerable. Perhaps a good clear non-technical introduction would be *The Substance of Mental Health* by George Preston, M.D., Farrar and Rinehart, N. Y., 1943, in which a state commissioner of mental hygiene gives brief practical views on how one comes by good mental health and how it may be passed on to others.

16. *Chadwick, Henry D., and Pope, Alton S. The Modern Attack on Tuberculosis* (2nd ed.). The Commonwealth Fund, N. Y., 1946. This new edition of a well known handbook contains fresh material on recent developments in administrative practice and control procedures, and has a bibliography.

17. *Handbook on Nutrition*. A Symposium. American Medical Association. Chicago, 1943. Some will say that this may be the best single volume which is readily accessible and covers the many

different parts of the general subject of nutrition.

18. *Vonderlehr, R. A., and Heller, J. R., Jr. The Control of Venereal Disease*. Reynal and Hitchcock, N. Y., 1946. As up-to-date as a printed text can hope to remain in this changeable and complicated special sector in disease control. The authors are well known U. S. Public Health Service staff members, and the Foreword is by Thomas Parran.

An earlier U. S. Public Health Service bulletin which is valuable but in need of revision is *The Principles of Venereal Disease Control* by Nels A. Nelson, Supplement No. 17 to *Venereal Disease Information*, Washington, 1942. Beside the many other publications of the U. S. Public Health Service on venereal disease control, the health officer will wish to know that a like series emanates from the American Social Hygiene Association, 1790 Broadway, N. Y., and may wish to secure from the latter source the looseleaf *Digest of Laws and Regulations* governing the venereal diseases in the several states, and a similar digest of state and federal laws dealing with prostitution.

19. *Ehlers, Victor M., and Steel, Ernest W. Municipal and Rural Sanitation* (3rd ed.). McGraw-Hill, N. Y., 1943. Perhaps as good a single volume on general sanitation as may be found.

For public health laboratory work *Standard Methods for the Examination of Water and Sewage* (9th ed.), American Public Health Association, N. Y., 1946, is essential; and also *Standard Methods for the Examination of Dairy Products* (8th ed.), American Public Health Association, N. Y., 1941; a ninth edition is in preparation; and *Diagnostic Procedures and Reagents* (2nd ed.), American Public Health Association, N. Y., 1945.

In its special field, *Milk and Food Sanitation Practice* by H. S. Adams, The Commonwealth Fund, N. Y., 1947,

is a good text with illustrations, bibliographies and helpful appendix material. G. M. Dack also has a helpful book entitled *Food Poisoning*, University of Chicago Press, Chicago, 1943.

20. *Sappington, C. O. Essentials of Industrial Health*. Lippincott, Philadelphia, 1943. The literature on industrial hygiene is extensive and possibly if one volume is to be on the bookshelf, this broad-range text with illustrations may be a good selection.

21. *Wood, Edith Elmer. Introduction to Housing. Facts and Principles*. U. S. Housing Authority, Superintendent of Documents, Washington, D. C. (about 1940). Illustrated. This is an excellent and authoritative pamphlet on basic housing facts and principles which are of concern to every community determined to clear its slums and provide decent homes for families of low income.

Any health officer interested in housing will wish to have on his bookshelf *Housing for Health*, a series of papers presented under the auspices of the Committee on the Hygiene of Housing of the American Public Health Association, N. Y., 1941. In this 221 page pamphlet there is much basic public health and philosophy from an active minded Association committee. In the appendix appears the committee's "*Basic Principles of Healthful Housing*" in which are listed thirty specific characteristics of housing whose direct influence upon health has not been successfully challenged. The "Basic Principles" have also been reprinted separately by the Association (2nd ed.), 1946.

22. *Steiglitz, Edward J. The Second Forty Years*. Lippincott, Philadelphia, 1946. A medical master approaches the problems of geriatrics and the biology and health of growing old. A nontechnical discussion of a public problem no health officer can ignore.

23. *Sydenstricker, Edgar. Health and Environment*. McGraw-Hill, N. Y.,

1933. A challenging document on health in relation to geography, and economic, social and occupational environment.

24. *Zinsser, Hans. Rats, Lice and History*. Little, Brown, Boston, 1935-1941. With crackling humor the author writes a biography of typhus. A wise and witty record of a battle over a span of 1,500 years and down to the time of DDT. Most health officers know that they may not safely or officially ignore the rat or the louse or the flea. This book will make their tasks more pleasant.

Zinsser's dying autobiography *As I Remember Him* is written as if in the third person, and was first published in June, 1940, by Little, Brown, Boston. A remarkable book which describes the life and philosophy of a physician and bacteriologist whose researches took him to the far corners of the earth.

25. *Freeman, Allen W. Five Million Patients*. Scribner, N. Y., 1946. A varied and human record of forty years in public health by a true friend to our profession who never once departs from "the third person" in this autobiography of the health officer-professor.

HISTORICAL WORKS, REFERENCE VOLUMES, PERIODICALS AND OTHER PUBLICATIONS

Before leaving the more particular for the more general volumes that might adorn a health officer's bookshelf, it is well to call attention to the book reviews that appear in each issue of the *American Journal of Public Health* and to the invaluable 29 page pocket-size *Bibliography on Public Health and Allied Subjects* that may be had for the asking and is published annually (25th ed., September, 1947) by the American Public Health Association, 1790 Broadway, N. Y. 19. It is indexed by subjects and ends with a special list of *Basic Books for Public Health Workers*. History. Reference has been made to

the history of public health but the following titles may here be added: Garrison, F. H. *An Introduction to the History of Medicine* (4th ed.), Saunders, Philadelphia, 1929; Vallery-Radot, R. *The Life of Pasteur*, translated by Mrs. Devonshire, Constable and Co., London, 1902 and 1921; Ravenel, M. P. (Editor), *A Half Century of Public Health*, American Public Health Association, N. Y., 1921; Smith, Stephen, *The City That Was*. Frank Allaben, N. Y., 1911; Wong, K. C. and Wu, Lien-Teh. *History of Chinese Medicine*, Tientsin Press, Tientsin, China, 1932 (Do you know the story of Chang Chung-ching, the Hippocrates of China and its greatest physician, who served as mayor of Changsha at about 196 A.D., and who is remembered chiefly because of his ten volume Essay on Typhoid?); the *Bibliography and Reference Notes*, in the December, 1943, issue of *Baltimore Health News*, which follow the article "Baltimore's Health Service 150 Years Old"; Duran-Reynals, M. L. *The Fever Bark Tree*. Doubleday, N. Y., 1946, in which the historic pageant of quinine is set forth in vivid color against a world-wide backdrop of malaria from the time it killed Alexander the Great down to Bataan and Corregidor and the chemical synthesis of quinine by R. B. Woodward and W. E. Doering at Harvard; and perhaps one of the most readable collections of brief biographies of *Pioneers of Public Health* (under that title), by M. E. M. Walker, Oliver and Boyd, London, 1930. Here we find staccato phrases such as: Edward Jenner, "vaccine clerk to the world"; Edwin Chadwick "among the best abused men of his time," of whose famous report of 1842 on the *Sanitary Condition of the Labouring Population of Great Britain* "ten thousand copies . . . were sold and distributed to the public"; William Farr, failing to become Registrar General of England; and Sir John Simon in a subordinate

position under the poor-law staff!—re-signing in full vigor from brilliant scientific and administrative service, but preserved to write the classic *English Sanitary Institutions*. In the Simon essay Mrs. Walker quotes from Lord Palmerston's famous reply of October 19, 1853, to the Edinburgh Presbytery's appeal for a great religious fast to stay the cholera. In it Lord Palmerston indicates his feeling that a fast is not suitable, but rather the purification of the poorer portions of the towns, to free them from the sources of pestilence which otherwise would remain "in spite of all the prayers and fastings of a united but inactive nation."

Reference volumes. Certain reference texts are needed in any health department, and the bookshelf may well include: a large *Webster's Dictionary*, Merriam, *Dorland's American Illustrated Medical Dictionary* (20th ed.), Saunders, 1944; the *American Medical Directory* (17th ed.), American Medical Association, 1942 (a new edition is soon to appear); *The World Almanac*, N. Y., 1948, or perhaps even better the new *Information Please Almanac—1948*, (2nd year), address 444 Madison Avenue, N. Y. 22; *Administrative Medicine*, edited by Haven Emerson, Thomas Nelson, N. Y., 1941; *A Manual of Style*, University of Chicago Press, Chicago, 1938 or later (an invaluable guide for the preparation of written or printed material, planning, composition, usages, type specimens), and beside the *Manual of Style* for written or printed material may rest a companion volume, *The Public Speakers' Treasure Chest*, by Herbert V. Prochnow (5th ed.), Harper, N. Y., 1942 (a text prepared for the man or woman "who must occasionally make an address, introduce a speaker, or preside at a meeting," which contains sound guidance on the preparation and delivery of a speech, and is chiefly a rich storehouse of selected quotations, biblical and other-

wise, phrases, similes, definitions, facts, humorous stories and jests that may often be of great aid and comfort not only to the speaker but to his audience); *Reports on Population*, Vol. 2 (for any given state), *Characteristics of the Population*. U. S. Bureau of the Census, 1940 (and other Census Bureau publications, national, state, and local population series, and housing series); and the 11th edition of the *Encyclopaedia Britannica* (29 volumes, India paper), Cambridge University Press, N. Y., 1910-1911. This is perhaps the last of the genuine "British" editions and can be purchased second-hand for about \$30, which is a treasure-bargain for the non-owner.

Standard medical texts are best selected according to taste. Two may be mentioned: *Osler's Principles and Practice of Medicine* by Henry A. Christian (16th ed.), Appleton-Century, N. Y., 1947; and *Holt's Diseases of Infancy and Childhood* (11th ed.), Appleton-Century, N. Y., 1939. And speaking of Osler, do not overlook his *Aequanimitas* (1904), *The Alabama Student* (1908), *The Evolution of Modern Medicine*, Yale University Press, 1921; not to mention the two-volume biography of Osler by Harvey Cushing.

Legal reference works that are essential are: The latest editions of the state public health law and any state sanitary code or state board of health regulations, any pertinent city or other local charter and its public health section; any city or other local code of health ordinances, including those on nuisance control, milk control, or housing, and related regulations. Good references to national legislation on public health both in the United States and Canada appear in the 3rd edition of Tobey's *Public Health Law*, and for the United States in Smillie (No. 11 above).

PERIODICALS AND OTHER PUBLICATIONS

No health department can do without

current periodical literature. Among the journals one may consider first the one in which this article appears, then the *Journal of the American Medical Association*, and particularly its annual hospital issue (as, April 12, 1947), then the *Canadian Public Health Journal* with its series of practical and stimulating articles, the *Bulletin* of the Pan American Sanitary Bureau, *Public Health Nursing*, *Hygeia*, and perhaps the *Journal of Industrial Hygiene and Toxicology*. But the question will still remain: Do we read and study the articles, editorials, and book reviews as we should?

Among other publications of great value a fair number will come to the health department for the asking. Most health officers know the gentle art of getting on a mailing list and sending for a reprint. There are the periodicals of federal, state, and local health agencies, official and nonofficial. First the weekly *Public Health Reports*, and occasional *Supplements* (such as the *Directory of State and Territorial Health Authorities*, 1947 which came in as this article was being written, and a like listing of local health officers, both revised periodically) of the U. S. Public Health Service, and its *Veneral Disease Information*, its *Industrial Hygiene Newsletter*, and its series of special *Bulletins*; then *The Child*, published monthly by the U. S. Children's Bureau, and many special bulletins from this source; the weekly *Health News* of the New York State Department of Health, Albany, N. Y. (truly a continuous post-graduate correspondence course in itself), the monthly *Bulletin* of the National Tuberculosis Association, and *Cancer News* published each month by the American Cancer Society, Inc. To these may be added the very worth while monthly *Think* which is generously distributed by International Business Machines Corporation, Think Magazine, 590 Madison Avenue, N. Y. 22. "And," as the Irishman would say:

"others too numerous to mention."

In reply to a plea for assistance in preparing this booklist, a former president of the American Public Health Association has written "And in closing may I suggest one volume which perhaps does not appear on a lot of health office shelves but its use in providing

succinct ideas, phrases and expressions for publicity and public health education purposes" is of greatest excellence, "so I hope that when I have the opportunity to visit your office . . . I shall find it on your shelf, namely the Holy Bible, both Old and New Testaments." To which, Amen.

Examinations for Permanent Corps, U. S. Public Health Service

Examination for appointment to the Regular Corps of the U. S. Public Health Service for the grades of Assistant Sanitary Engineer and Senior Assistant Sanitary Engineer will be held in June, 1948. About 15 appointments are to be made. Application forms and additional information can be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C. Applications must be filed with the Surgeon General prior to June 1, 1948.

Applicants for the Assistant grade must be at least 21 years old and United States citizens, must possess a degree in engineering, and must have had at least 7 years of education (ex-

clusive of high school) and professional training or experience, at least 2 years of which shall have been of a professional nature in public health or a related field.

An applicant for the Senior Assistant grade must meet the requirements for the Assistant grade and have in addition 4 more years of education and professional training or experience. A total of at least 6 years shall have been of professional training or experience in public health.

The starting yearly salary, with dependents, for the Assistant grade is \$3,811 and for the Senior Assistant \$4,351.

Current Status of Immunization Procedures

Vaccination Against Smallpox *

R. S. MUCKENFUSS, M.D., F.A.P.H.A.

Bureau of Laboratories, New York City Health Department, New York, N. Y.

PROTECTION against smallpox by cutaneous inoculation with the virus of cowpox, is the oldest and probably the most effective method of specific disease prevention. The essential facts concerning vaccination are so well known that a reference to recent reviews by Robinson;¹ by Ross,² and by Eley³ suffices with regard to the essentials of the preparation and characteristics of smallpox vaccine and the complications affecting its use.

In April, virulent smallpox appeared in New York City under circumstances that made it impossible to tell how widely it was seeded or to be sure that all contacts had been located. This outbreak has been described elsewhere at this meeting by Commissioner Israel Weinstein.⁴ The decision was made to vaccinate as many residents of the city as possible, and it was estimated that more than 6 million vaccinations were performed.

Mass vaccination on such a scale was a unique experience, and presented a few problems that are not usually encountered. This paper is based on that experience.

Type of Reaction—A fairly representative sample of results is available as a result of the foresight of Dr. Margaret W. Barnard, who instructed the

district health officers to follow up the results of vaccination in health centers. Records of over 60,000 vaccinations were made. These are not yet analyzed, but this is being done and will be reported in detail by Dr. Morris Greenberg before the New York Academy of Medicine. It may be stated with certainty, however, that well over half of those vaccinated showed either primary or accelerated reactions. This is taken as evidence that the susceptible population was sufficient to make a major epidemic possible.

Although some reactions were fairly severe, resulting in loss of time from work, there were no complaints to the Health Department. Perhaps the fact that a sore arm indicated the need for vaccination accounted for the lack of complaints.

The supply of vaccine constituted a major problem. If scheduling over a period of a number of days were possible, this would have been comparatively easy of solution. However, rapid dissemination of news and advice by newspaper and radio resulted in a sudden crowding of clinics and physicians' offices. On the day when the situation was most acute, I had on my desk orders for over 3 million vaccinations. Smallpox vaccine is a perishable product and it is obvious that it is impossible to maintain a reserve of this size without accepting prohibitive losses.

The problem was met by increasing manufacture as rapidly as possible as

* Presented at a Joint Session of the Epidemiology, Health Officers, Laboratory, Maternal and Child Health, and School Health Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

soon as the diagnosis of the first cases was made. Vaccine was distributed in 1 ml. vials, sufficient for 50 or more vaccinations, accompanying each vial with 50 sterilized toothpicks for use as applicators and 50 sterilized needles. As soon as the decision for general vaccination was made, arrangements were made by Mayor O'Dwyer to borrow all available surplus from the Army and Navy, and these supplies were replaced after vaccination in New York City was completed.

Vaccine was purchased in 1 ml. vials, and applicators and needles were packaged and sterilized in the laboratory. It was necessary for the entire laboratory staff to devote all available time to the packaging of needles and applicators. For a time supplies were so short that it was necessary to ask clinics to sterilize and reuse needles.

Standard packages in capillary tubes, suitable for office use, were not available in sufficient quantity to meet the needs of physicians. However, all such packages were made available to physicians and were not sent to clinics.

It is possible that the problem of supply might become critical if smallpox were introduced simultaneously into several thickly populated areas of the country.

Generalized vaccinia did occur, and 36 cases were reported to the Department of Health. Twenty-two of these cases occurred in children who had not themselves been vaccinated but who acquired vaccinia by contact from other members of the family. Two of these children died. Although vaccinia by

contact in eczematous children has been well described^{5, 6} it is not often mentioned in textbooks. It should be emphasized that the presence of a case of eczema is a contraindication to vaccination of any member of the household.

Post-vaccinal encephalitis was reported, and all reports were investigated. Forty-two cases met reasonable criteria for this diagnosis, an incidence of approximately 1 per 150,000. Of 8 deaths reported, 4 were demonstrated at autopsy to be meningitis, tumor, or thrombosis. The other 4 have been examined by pathologists in the city, and the pathological changes characteristic of post-vaccinal encephalitis have not been found. Thus, the diagnosis cannot be considered proved in these cases.

SUMMARY

In vaccinating over 6 million people, the problem of supply was met by emergency packaging. The rate of occurrence of unavoidable complications was so low as to constitute a negligible danger as compared to the danger of a major smallpox epidemic.

Current Status of Immunization Procedures

Pertussis *

JOSEPH A. BELL, M.D.

Senior Surgeon, Division of Infectious Diseases, National Institute of Health, Bethesda, Md.

THE current status of pertussis immunization may be taken arbitrarily to cover the developments of the past 10 years. Ten years ago there were many who were skeptical of the protective value of pertussis vaccine, but since then many studies have been reported, all of which have contributed in a large or small way to our knowledge of pertussis immunization. All these studies cannot here be reviewed, hence the discussion will be limited to the general public health use of pertussis vaccine and in so far as possible it will exclude those phases of the subject which are of basic concern to the private practising physician.

It is generally recognized that both the health officer and the private practising physicians are jointly responsible for the health of the individual and the health of the community. Their obligations differ in that the private physician is basically responsible for the health of his individual patient whereas the health officer is basically responsible for the health of the community.

This difference in basic obligations leads to a diverse use of pertussis vaccine. The private physician seeks to induce and maintain the highest practicable protection against pertussis for his

patient. The kind of vaccine he will use, the size of dose, the number of doses, the intervals between doses, and the age at which he will give the vaccine may vary considerably depending upon the specific situation and the individual need of his patient. He will encounter many individual situations in which he will be obligated to use vaccine in a manner for which scientific proof of value is not available. The public health officer, on the other hand, has a different aim. He seeks to induce and maintain a level of immunity in the general population which, within practical limits, will prevent or ameliorate a substantial proportion of the suffering, inconvenience, disability, and loss of life which occur in the community as the result of pertussis. His public obligation requires that in routine practice he should use only vaccine products which have been adequately demonstrated to confer protection, and that he should use these products in a manner which has been adequately shown to have value in fulfilling his basic obligation to the community.

There have been many studies on pertussis vaccine but they differ from each other in many respects. They utilize different methods of preparation of the vaccine, different dosages, different intervals between doses, and different study procedures. The study procedures differ as to environmental groups studied, as to adequacy of observation, in

* Presented at a Joint Session of the Epidemiology, Health Officers, Laboratory, Maternal and Child Health, and School Health Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

method of selection and treatment of controls, and in criteria for evaluating protection against pertussis. Thus, it is impossible to make direct comparisons between the various studies, and one cannot arrive at a satisfactory conclusion as to which is the best product and what is the best method of administration.

Considering each study separately, however, one can safely conclude that certain vaccine products have given substantial protection against clinical pertussis and that other products have no demonstrated value. Unfortunately there is as yet no known quick and effective way of determining for certain that a particular vaccine preparation will be effective. A relatively new mouse protection tests has been developed which looks promising for this purpose. The ultimate value of this new test must await epidemiological trial to determine whether mouse protection parallels human protection. It is recognized that cholera and typhoid vaccines are accepted for public health use on the basis of a mouse protection test, but here the nature of the test is somewhat different and further developed than for pertussis, and the use of these vaccines is not as widespread as that indicated for pertussis vaccine.

The vaccines which have been shown to have value in field trials in the general population may be classified as fluid vaccines, alum-precipitated vaccines, and mixed vaccines. Of the fluid vaccines, there is good evidence that the fluid vaccine prepared as described by Dr. Kendrick has given substantial protection against clinical pertussis. Three or four doses of this product, representing a total of 70 to 80 billion organisms, and given at weekly intervals between doses, to young children 6-35 months of age, have demonstrated value. The difference in the method of preparation of this vaccine and that described by Dr. Sauer is probably of no great

importance to their effectiveness for general use.

Of the alum-precipitated vaccines, there is good evidence that the A-P pertussis vaccine prepared as described by Dr. Harrison and his associates will give substantial protection against clinical pertussis. Three doses of this product representing a total of 30 billion organisms given with a 1 and 3 week interval between doses to children 6-35 months of age have demonstrated value. Also, two doses of this product representing a total of only 20 billion organisms and given with a 4 week interval between doses to children 2-35 months of age, have given demonstrated protection. The A-P vaccine has been shown to be effective in young children when given at 2-5 months of age.

Of the alum-precipitated mixtures of diphtheria toxoid and pertussis vaccine, an A-P mixture of pertussis vaccine and diphtheria toxoid prepared as described by either Dr. Kendrick or by Dr. Bell has similarly been shown to confer substantial protection against clinical pertussis. Three doses of this product, representing a total of 30 billion organisms and given with a 1 and 4 week interval between doses, gave protection against pertussis. The three doses of the A-P mixed product gave good protection against diphtheria as measured by blood-antitoxin titrations. Furthermore, two doses of the A-P mixed product, containing a total of 20 billion organisms and given with a 4 week interval between doses, gave substantial protection against clinical pertussis when administered at either 2-5 months of age or at 6-23 months of age. The two doses of the mixed product incidentally gave better protection against diphtheria than an equivalent amount of comparably given A-P diphtheria toxoid as measured by the Schick test.

Reactions reported due to the above mentioned products have not been of sufficient significance to contraindicate

their use. It is important to recall, however, that these products have not yet been used on the scale that diphtheria toxoid and smallpox vaccine are now employed. Long experience with other and similar vaccines has shown that their benefit far outweighs their dangers. This seems likely with pertussis vaccine.

It is believed that health officers have sufficient evidence to permit the use of any of the above mentioned products. It is highly desirable that pertussis immunization should begin early in life, as the peak of deaths reported from this disease is at 2 months of age. Certain dangers attend the general use of any injection of any kind at this very young age. The death rate from all causes during the first few months of life is comparatively high;

thus widespread use of any vaccine during the first few months of life requires caution lest some of the deaths due to usual causes may be wrongly attributed to the vaccine.

In summary, there remains no reasonable doubt but that certain pertussis vaccine preparations have been adequately shown to confer substantial protection against clinical pertussis when given to the general population in a manner suitable for public health use. It is believed there is sufficient evidence at hand to warrant public health officers' consideration of pertussis vaccine for general routine use. Such routine general use of pertussis vaccine should be limited to the products which have been shown to be effective in fulfilling the health officer's obligation to the community.

Grants for Research in Human Reproduction

The Committee on Human Reproduction of the National Research Council, acting for the National Committee on Maternal Health, Inc., announces research grants in the field of reproduction. Applications to become effective July 1, 1948, will be received until May 1, 1948; those to become effective October 1, 1948, will be received until August 1, 1948.

The committee will consider support of biological, clinical, economic, medical, psychological, and sociological research dealing broadly with the field of human reproduction in general and with respect to specific problems including maternal

and fetal physiology, the factors controlling conception, the physiology of fertilization and conception, and sterility. For the year 1948-1949, the committee will place specific emphasis upon investigations of the factors controlling conception, fertility, and sterility, but other fields of endeavor will be supported if projects of special significance are presented. In subsequent years, changing emphasis may be anticipated.

Applications should be addressed to Committee on Human Reproduction, National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

Current Status of Immunization Procedures

Typhoid Fever *

RUFUS L. HOLT, COLONEL, M.C.

*Commandant of the Army Medical Department, Research and Graduate School,
Army Medical Center, Washington, D. C.*

SINCE 1940 the Army¹ has routinely used the polyvalent TAB vaccine as we are fully aware of the fact that monovalent typhoid vaccine will not protect against massive doses of *Salmonella paratyphi* and *S. schottmuelleri* and that under field conditions we could expect to suffer from outbreaks produced by these organisms.

The military services have known for some time that doses of vaccines prepared from our strains of *Eberthella typhosa* and *S. schottmuelleri* would produce antibodies against each other and that this characteristic lessened the likelihood of *S. schottmuelleri* infections under field conditions. The *S. paratyphi* fraction in our vaccine does not produce protective antibodies specific for either of the other organisms used in the vaccine, nor do the *E. typhosa* and *S. schottmuelleri* vaccines produce specific antibodies for *S. paratyphi* sufficient to protect. Experimental evidence has shown this to be true even though all three strains share the XII antigen of the Kauffmann and White schema. The homologous immunity produced by *S. paratyphi* is good but we have had more outbreaks of para A fevers than is the case with para B.²

After considerable investigation it was decided to adopt strain 58 as our typhoid antigen. It was and is secured from a carrier in Panama. It is culturally and biochemically typical, produces smooth colonies, is highly virulent, and is antigenically complete with a high content of Vi antigen. Most if not all commercial producers now use this strain. Hundreds of freshly isolated strains have been checked against strain 58 and there is no evidence that any of them are superior for vaccine production. Strain 58 protects as well against all strains we have received as does any other strain with which we are familiar.¹ Presently used strains of *S. paratyphi* and *S. schottmuelleri* were selected following similar trials and are constantly under check in the same manner. We are not satisfied with the presently used strain of *S. paratyphi* but have not been able to find a better one.

It is not likely that we will secure better strains of *E. typhosa* or para B nor that immunogenic powers can be enhanced much as a result of further purification of the vaccine. It is much more likely that we shall attack the problem by fractionation of the organisms. It is well established that an essential immunizing fraction is a polysaccharide which can be secured by acid or enzymic hydrolysis of the acetone-insoluble portion of the organisms.³ So far, attempts to isolate antigenically

* Presented at a Joint Session of the Epidemiology, Health Officers, Laboratory, Maternal and Child Health, and School Health Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

active fractions which are entirely free of nitrogen have been unsuccessful.

Reactions following use of the present type of vaccine can be lessened somewhat by modification of the dosage pattern and without detectable lowering of the immunity produced. Exhaustive research definitely indicates that three doses of 0.5 ml. subcutaneously, with intervals of 7 days between doses, actually produce higher titers of protective antibodies than is the case with the standard dosage. There were fewer and less severe reactions from this modified dosage and we are of the opinion that this means of initial immunization should be adopted.⁴ Intracutaneous administration of small amounts of vaccine as an initial immunizing procedure is not advisable except in the old and debilitated, but such a method as a booster dose is acceptable and produces an increase of immune bodies equal to, or in excess of, that produced following the subcutaneous injection of 0.5 ml. For initial sensitization and antibody production one must use at least a series of doses of 0.5, 0.5, and 0.5 ml. of the vaccine.⁵ The agglutinin rise is comparable to the rise in mouse-protective titers but the level of the titer of agglutinins ordinarily drops more rapidly and may disappear while considerable amounts of protective antibodies are still present. The amount of protection afforded by proper inoculation of typhoid vaccine varies widely with the individual as well as with the antigenic quality of the vaccine administered. It is probably safe to say that protective immunity against ordinary hazards of infection can be expected to result, and that such immunity will continue for about one year, after which booster doses should be administered.⁶ In rare cases no detectable immunity ensues and none can be developed.

While we secure antibodies as a result of the injection of antigenic fractions of bacteria other than Vi we

depend upon Vi antibody to prevent the contraction of disease due to *E. typhosa*. We are now working on the possibility of fortifying our vaccine by the addition of Vi antigen from an *Escherichia coli* strain the antigenic pattern of which varies markedly from that of *Eberthella typhosa*.⁷ This organism has no antigen in common with *E. typhosa* with the exception of the Vi fraction. We have been able to secure as good immunity to typhoid organisms in small animals by the use of this heterologous Vi antigen as was obtained by the use of Vi antigen obtained from *E. typhosa*. Toxicity experiments in man indicate that it will be safe to use it for immunity production and thus perhaps eliminate most if not all of our reactions. Much work remains to be done before it can be recommended as a replacement for the typhoid fraction of the vaccine. We know little of the production of antibodies in man, but it would appear that Vi antigen acts as a protective substance for the invading typhoid organism and that in the absence of Vi antibody the other immunity mechanisms cannot function. O antigens produce antibodies whose chief if not sole function is to neutralize endotoxins released at the time the organisms disintegrate. If, as we believe, this is the case, then Vi antigen alone may be an acceptable substitute for the present typhoid vaccine. From this belief stem our present efforts to produce a vaccine with a high immunizing power and a low reaction rate.

We do not believe that oral administration can compare with the subcutaneous method, and do not advise its use under any conditions.

As a result of vaccination with TAB vaccine we not only lower the case rate but we also lower the mortality rate. This latter feature was again emphasized last year by Syverton and others⁸ in the report of an outbreak originating in Okinawa. There were no deaths in 24

cases, 3 typhoid and 21 para A cases. Although the symptomatology and physical findings are essentially the same as in cases occurring in the unvaccinated, the mortality appears to be markedly reduced. The duration of the disease does not appear to be affected.

The role of carriers in the production of typhoid is most important, especially since they are the source of most if not all of our explosive outbreaks. It is our firm conviction that carrier rates have been reduced in proportion to the reduction in case rates and that they now constitute an extremely small percentage of our military population.

That protection does result from typhoid vaccination can hardly be denied in face of the experience gained in the two world wars.^{9, 10}

The statements made on Army experience cover a period of about forty

years and are based on a total of at least 30 million inoculated individuals.

The chart * presented covers the level of typhoid infection in the Army during the Civil War, the Spanish-American War, World War I, and World War II. It will be noted that in the latter case the figures are shown as they apply to the Army at home and abroad. These figures are released to the public for the first time on this occasion. The strength of the Army is still restricted information, but it can be said that we had only a few hundred cases of typhoid among several million troops during a period of five years.

* Chart was prepared by Brig. Gen. George R. Callender, MC, to include figures for 1941. Figures for 1942-1947 were added by the author.

Current Status of Immunization Procedures

Tetanus, and Exotic Diseases of Military Importance *

ARTHUR P. LONG, LT. COL. M.C., U.S.A., F.A.P.H.A.

Infectious Disease Control Branch, Office of the Surgeon General, Washington, D. C.

ACTIVE immunization against tetanus, advocated for use in human beings about twenty years ago, has now been widely accepted.¹ The experience with tetanus immunization in the British and American Armies has been quite completely summarized elsewhere.^{2,3} In reporting British experience, Boyd² concluded that the incidence of tetanus in African and European campaigns was negligible. He attributed this result largely to active immunization with tetanus toxoid, although it was the British practice to administer a prophylactic dose of antitoxin (3,000 International Units) as soon as possible after an injury rather than a stimulating dose of toxoid as was done for American troops.

In the United States Army but 12 cases of tetanus are known to have occurred during the period 1942 through 1945. Only one of these developed among the approximately one-half million troops reported to have been wounded. Of the 12 cases, 6 were in individuals with no active immunization, 2 in soldiers who had been basically immunized but had received no post-injury toxoid, and 4 in those whose records indicated that they had received the basic immunization plus the emergency stimulating dose at the time

of injury. Five fatalities occurred, 2 of them among the 4 who had received the full course of toxoid. In the United States Navy, a total of 4 cases was verified, only 1 occurring in an individual receiving the prescribed toxoid prophylaxis.⁴ Taking into consideration the number of individuals involved, the incidence of tetanus was essentially the same in the Army and Navy groups.

In the Japanese Army and Navy, where routine immunization was not practised, it was reported that from 1940 through 1944 tetanus occurred in about 10 per 100,000 wounded men, an incidence greatly in excess of that experienced in the American Army. A report from the unimmunized German Ground Forces in Normandy indicated more than 80 cases of tetanus, though none occurred among the immunized Luftwaffe personnel. During the Manila operation, over 400 cases and more than 300 deaths from tetanus in civilians were reported. Viewing this total experience, there can be no question that active immunization with toxoid is an effective means for the prevention of tetanus even under the severe conditions imposed by wounds and injuries incident to military operations.

The risk of tetanus in civilian populations under normal conditions is even more difficult to assay than that in military groups. There is no question, however, but that a certain risk does exist. The mortality rate from tetanus following injuries (including tetanus neon-

* Presented at a Joint Session of the Epidemiology, Health Officers, Laboratory, Maternal and Child Health, and School Health Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

also be available for the ensuing season.

A proposed vaccination procedure involves the administration of three doses of 1 ml. each, the first two 1 week apart and the third approximately 30 days later.

Courses in Laboratory Diagnosis of Parasitic Diseases

The U. S. Public Health Service in February completed the first of three refresher courses to be given during 1948 on the laboratory diagnosis of parasitic diseases by the Laboratory Division of the Communicable Disease Center in Atlanta. Two later courses will be given from July 12 to August 20, and October 11 to November 19.

This training is open to all grades of employed laboratory personnel. Although priority must be given to the laboratories of state and local public health departments, applicants from hospitals and

private laboratories will be accepted if vacancies occur. There will be no tuition or laboratory fee, but travel and living expenses must be paid by the worker or his employer.

Applications should be made as early as possible since acceptance notifications are made approximately two months before the course begins. All inquiries should be addressed to R. F. Reider, Surgeon (R), Assistant Chief, Laboratory Division, Communicable Disease Center, 291 Peachtree Street, Atlanta, Ga.

It has been determined by blood-antitoxin-level determinations in soldiers* that this regime results in adequate protection after the initial series of toxoid injections and that for a period of at least 4 to 5 years after the single stimulating dose the circulating antitoxin level can be effectively raised within 1 week by the so-called emergency or booster dose. Findings in adults, who received fluid toxoid, are essentially the same as those of McBryde and Poston⁷ in children following immunization with the alum-precipitated agent. These workers demonstrated satisfactory responses to booster doses 4 and 5 years after completion of the basic series. Further experience will be required to determine just how long this period of responsiveness will ultimately prove to be.

EPIDEMIC TYPHUS FEVER

The vaccine currently used for protection from epidemic typhus fever is a suspension of formalin-killed epidemic typhus rickettsiae and soluble antigen obtained by cultivation of the organisms in the yolk sac of fertile hens' eggs.⁸ It is administered in 2 subcutaneous doses of 1 ml. each given with an interval of 7 to 10 days between doses. Additional stimulating doses of 1 ml. each are considered desirable every 4 to 6 months in the presence of the disease. At the present time, while there is no serious epidemic typhus situation in the world, this vaccination is considered desirable for those who are to travel or reside in east or southeast Europe, Asia, and Japan. Since epidemic typhus is known to occur in Mexico and certain sections of Central and South America, individuals traveling to these areas might also be well advised to be vaccinated against typhus if freedom from louse in-

festation cannot be assured. It is emphasized that epidemic typhus vaccines contain epidemic louse-borne typhus antigen only and hence cannot be expected to produce protection from the endemic or murine type of the disease. However, a vaccine for protection against this form of the disease is now available.

CHOLERA

It is now the general consensus that in areas where cholera is frequently encountered, vaccination with the best vaccine available should be practised in addition to the usual measures to prevent ingestion of the cholera vibrio. The vaccine obtainable in this country and currently used, when indicated, for military personnel, consists of a suspension of 8 billion phenol-killed cholera vibrios per ml. The organisms used are of the Inaba and Ogawa strains which are considered to be as fully virulent and antigenic as any obtainable at this time. Vaccination is accomplished by the subcutaneous administration of two doses of 0.5 and 1 ml. each with an interval of 7 to 10 days between injections. Subsequent stimulating doses of 1 ml. each are given at 4 to 6 months intervals in the presence of serious danger of infection. Experience in the American Army with this procedure added little to previous evaluations. The disease was present in epidemic or semi-epidemic proportions in a number of areas where troops were stationed, and only 13 cases occurred among them. These were in vaccinated personnel. No cases occurred among United States Forces in India although some were experienced in unvaccinated allied forces in the same area.

PLAGUE

The vaccine used is a suspension of 2 billion formalin-killed virulent plague bacilli per ml. The spacing and size of dosage, as well as the administration of

* The antitoxin titrations referred to were performed by Dr. M. V. Veldee and associates at the National Institute of Health, Bethesda, Md., and Dr. J. Howard Mueller, Department of Bacteriology and Immunology, Harvard Medical School.

torum) in the civil population of the United States was in the neighborhood of 0.7 per 100,000 for each of the three years 1936 through 1938. A breakdown of this incidence by age groups indicates that the period of childhood (up to age 15) holds the greatest hazard, and young adult life (age 25-34) the least. Tetanus neonatorum contributes heavily in the first year of life, the mortality rate for this period being 7.8 per 100,000. The next highest rate (1.2) was for the 5 to 14 year group. The special hazard to those subject to more than the usual risk of exposure to tetanus, such as farmers, horsemen and others whose activities increase the likelihood of injuries contaminated with tetanus spores is well recognized. For this group as well as for children, active immunization with tetanus toxoid would appear to be warranted, although the disease hardly represents a sufficient problem to require this procedure as a general public health practice.

The choice of immunizing agents lies essentially between fluid toxoid and the alum-precipitated preparation. The primary considerations in making this choice have been reviewed recently in some detail by Edsall.⁵ Both types are highly effective as demonstrated by the results in the United States Army and Navy; the Army using fluid toxoid and the Navy, alum-precipitated toxoid. Three doses of the fluid type are required for the basic immunization while two of the alum-precipitated agent will suffice. Since the addition of alum to an antigen may act to increase its sensitizing properties as well as to enhance its antigenicity, the possibility of reactions of sensitivity to repeated doses of alum toxoid is to be considered. However, the new methods for processing toxoids reported by Pillemer and his coworkers,⁶ may serve to minimize the likelihood of such reactions. In any event, it is extremely important that whichever type of toxoid is used be as free as possible

of non-toxoid constituents which might produce undesirable reactions. On theoretical grounds at least, fluid toxoid, because of its more rapid absorption, would appear to be the agent of choice for the emergency or booster dose at time of injury. However, there is no indication that the alum-precipitated material is not effective for this purpose. Combined antigens, such as diphtheria and tetanus toxoid or this combination plus pertussis vaccine, are now available. The utilization of such combinations appears reasonable if adequate doses of the individual antigens can be provided without resulting in undue reactions, local or systemic. It is to be recalled, however, that protection from pertussis is required at an early age when an optimal response to diphtheria toxoid may not be obtained.⁵ For the stimulating dose, tetanus toxoid alone, rather than in combination with other antigens, is preferred in order to minimize local and systemic reactions, particularly if stimulation is required in adolescent or adult life.

As indicated before, in using fluid toxoid, three doses of 1 ml. each, administered at intervals of 3 to 4 weeks, are required and with the alum-precipitated agent, two doses of $\frac{1}{2}$ to 1 ml. 4 to 8 weeks apart. In United States military usage, this basic preparation was followed at the end of the first year by a single stimulating dose of 1 ml. During the first part of the war, another stimulating dose was administered to all Army personnel departing for a theater of operations unless such departure was within 6 months subsequent to a previous dose. For the last three years, however, no more toxoid has been given after the first stimulating injection unless indicated by the occurrence of a wound or other injury which might result in tetanus. No antitoxin is administered for prophylaxis unless some doubt is entertained as to previous active immunization.

demonstration school of nursing where from 4 to 19 per cent of the students developed demonstrable tuberculous lesions and several died in the 1920's and early 1930's, no death has occurred in many years; only 2 students have developed lesions large enough to be demonstrated by x-ray inspection in the past 5 years, and the infection attack rate among nonreactors over the entire period of school years has decreased from as high as 100 per cent to less than 5 per cent. In 1928 33 per cent of all students entering the university reacted to tuberculin, and only

6.4 per cent in 1946. In the largest city the incidence of tuberculous infection among grade school children decreased from 47.3 per cent in 1926 to 7.7 per cent in 1944.

Eradication of tuberculosis at the grade school age level has been achieved in many schools. It is in store for many others. The epidemiological procedures that have produced these accomplishments are applicable anywhere. They require persistence, patience, and strenuous work. Moreover, they constitute the only known method by which tuberculosis can be eradicated.

Relationship of Tryptophane to the Incidence of Dental Caries*

NAOMI C. TURNER, Ed.M., AND GEORGE E. CROWELL, D.M.D.

Forsyth Dental Infirmary, Boston, Mass.

THE possibility that bacteria are a causative factor in dental caries has received major attention since the days of Miller. However, Miller's original experiment, in which saliva and bread pabulum led to decalcification of tooth structure, lends itself to two interpretations: (1) the multiplication of bacteria with the production of decalcifying acids; (2) the direct action of salivary enzymes on starch leading to decalcifying acids as a product from starch via a certain type of human enzyme system. These acids may in some manner be associated with the eventual disintegration of tooth structure *in vivo*. The bacterial approach has been emphasized, largely perhaps, because of the timing of Miller's work with the discoveries of Pasteur and the development of the germ theory of disease. It is to the relatively neglected enzyme system of the individual's own saliva and its action in the breakdown of starch as related to dental caries to which we would like to direct your attention.

Before presenting the evidence from our own studies, may we cite the work of two other investigators which suggests that salivary amylase may be one of the factors in the onset of the carious process. Victor Dietz¹ found that in initiating the carious process in a tooth *in vitro* by use of bread pabulum and saliva, with agitation, the saliva

must come from a mouth whose teeth show caries. Fosdick² found that the saliva of a caries-susceptible individual withdrew 11.1 mg. of calcium from 4 gm. of powdered human tooth enamel after 4 hours' agitation at room temperature; whereas, the saliva of caries-immune individuals withdrew no calcium under the same conditions.

In 1944, Turner and Crane³ reported a correlation between the dextrinizing time of saliva working on starch and the amount of caries in the mouth of the individual. Rampant caries was associated with rapidly dextrinizing saliva while freedom from caries was associated with slowly dextrinizing saliva. Since this time, additional evidence of this relationship has been secured. Some workers have reported similar results.⁴ Others have not found the correlation.⁵ This is not strange since the conditions of testing must be thoroughly rigid as to freshness of saliva, concentration of solutions, proportion of reagents, and also as to temperature. All must be regulated to satisfy the range of amylase activity.

After recognizing the existence of a relationship between the mode of starch breakdown and the degree of dental caries, a survey of the literature and particularly a consideration of the studies of Wohlgemuth⁶ in 1908, suggested the desirability of testing the effect of individual amino acids on the dextrinizing time of saliva working on starch. This also seemed logical because it had been shown that a diet high in protein

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

and low in carbohydrate⁷ has a retarding effect on dental caries.

Individual amino acids were added separately at 0.01 molar concentration to fresh saliva which was then mixed with starch solution. Some of the amino acids, notably glutamic acid, drove the dextrinizing time in the direction of salivas associated with caries. Tyrosine was without effect. Only tryptophane, among the amino acids tried, prolonged the dextrinizing time to a length comparable with the dextrinizing time of the salivas associated with freedom from caries. Indole and pyrrole produced similar results. Their structural similarity to tryptophane is well understood.

Since tryptophane significantly delayed the dextrinizing time of saliva working on starch, on the spot plate,⁸ it became of interest to watch its effect after ingestion. Preliminary studies indicated that the ingestion of crystalline tryptophane does, in fact, alter saliva's action on starch in the direction of a lengthening of the dextrinizing time. Early in these ingestions a drop in blood sugar was noted. This tendency we have confirmed with several groups. The desirability of further study of a possible relationship, of interest to the diabetic, is apparent.

For a moment, we will leave our consideration of tryptophane, for a further consideration of the nature and meaning of the dextrinizing test. *In vitro*, it was possible to run the scale of dextrinization from colorless, to purple (some-

times through green) to brown—forward and backward according to whether an oxidizing agent such as hydrogen peroxide or a reducing agent such as sodium hydro-sulfite was added. This finding suggested the possibility that, in the correlative factor, we might be dealing with highly oxidative versus more reductive salivas.

With this in mind several additional tests were devised. This step seemed desirable since the dextrinizing test used was tedious, exacting as to conditions, and difficult for some workers to duplicate. Further, we might by additional tests establish something more concerning the correlative feature.

These tests and their results are described in two previous articles.^{9, 10} We need not burden you with their detail. Suffice it to say that they indicated further that the correlative factor between saliva and caries may be associated with a biological oxidation-reduction process. They also indicated that acid production from the action of saliva on starch may have real significance for the carious state. With these tests we are able to distinguish two types of saliva with the characteristics shown in Table 1.

Characteristics one and three above remind us of the classical description of α and β amylase.¹¹ You will recall α amylase as that amylase which, with starch, quickly fails to give a blue or purple color with iodine and yet which is slow in the production of reducing material. On the other hand β amylase

TABLE 1

I. Caries associated saliva

1. Fast dextrinizing time, i.e., fresh saliva with 1% corn starch solution soon fails to give a blue or purple color with iodine.
2. Slow decolorization of preformed starch blue (redox + 300 \pm 10; pH 7 \pm 0.3), showing high oxidative capacity.
3. Low production of reducing material as measured with "clinitest" procedure.
4. High production of acid from starch in 2 hour incubation at room temperature as measured with 0.01 N NaOH, and phenolphthalein as indicator.
5. Low content of tryptophane or similar indole containing molecule.

II. Caries-free associated saliva

1. Slow dextrinizing time, i.e., fresh saliva with 1% corn starch solution gives purple color with iodine for longer periods of time.
2. Rapid decolorization of preformed starch blue (redox + 300 \pm 10; pH 7 \pm 0.3) showing high reductive capacity.
3. High production of reducing material as measured with "clinitest" procedure.
4. Low production of acid from starch in two hour incubation at room temperature as measured with 0.01 N NaOH, and phenolphthalein as indicator.
5. High content of tryptophane or similar indole containing molecule.

with starch gives a blue or purple color with iodine for a longer period of time and yet relatively quickly produces reducing substance. We seem to have a distinct difference in the mode and pathway of starch breakdown by these two amylases. Similarly, in the two types of saliva the intermediate products from starch degradation and their disposition may be at variance.

This battery of confirmatory tests was especially useful when a small group of young adults, who reported 7-10 cavities in the previous 6 months, volunteered to ingest crystalline tryptophane for a test period of 3 months. Such a small, medically controlled pilot study seemed desirable before a more extensive clinical trial of the effect of tryptophane.

A physician's examination and laboratory tests of urine, saliva, and blood preceded and followed the tryptophane ingestions. The latter were adjusted to body weight and regulated as to frequency by direct salivary test for tryptophane. Eight individuals constituted the pilot group. Four ingested tryptophane and four served as controls. There was no significant change in blood pressure or in body weight for either group. The average blood sugar drop for the pioneer group was held to nine points.¹² It is necessary to keep in mind this blood sugar drop and to regulate the dosage carefully in order to avoid hypoglycemia. Probably hemoglobin also

should be watched during tryptophane ingestions until such time as the evidence on this point is clear. The results of this pilot study are summarized in Table 2 which also gives average figures for the many "rampant caries" and "caries-free" individuals previously studied.

We see here that after the ingestion of tryptophane, acid production from starch is lessened in a 2 hour period at room temperature; and there is a corresponding increase in the production of reducing material. Decolorization of preformed starch blue is hastened and our evidence with this small group suggests a beneficial effect on the caries rate, but we do not regard our evidence as sufficiently extensive to report on this phase of the study.

There are interesting theoretical implications in the fate of carbohydrates under tryptophane ingestion. It has been shown that starch is a source of both oxalic acid^{13,14} and glyoxal.¹⁵ Among chemists tryptophane's tendency to condense with aldehydes is well known. In this tendency may lie the explanation of the possible value of tryptophane as a caries deterrent. Given an enzyme system in which tryptophane is an adjunct, one might expect that, in the aldehyde stage of starch degradation before the additional oxidative step leading to acid production, tryptophane would condense with the aldehyde, thus preventing the aldehydes from being

TABLE 2
Pilot Study

| | <i>0.01 N Acid per ml. saliva and starch</i> | <i>Reducing sub- stance as meas. by Clinitest</i> | <i>Decolorization Time</i> | <i>Rampant Decay</i> |

| After Tryptophane | 0.088 ml. | 0.312% | 5 min. | 1 of 4 * |
| RAMPANT CARIES | 0.323 ml. | 0.163% | 23 min. | All |
| CARIES-FREE | 0.04 ml. | 0.309% | 5.2 min. | None |

* The individual whose caries rate was not appreciably decreased had recently had poliomyelitis, and the salivary tryptophane was not built up to the optimal level until the end of the experiment.

Tyrosine Sheaves from Saliva

further oxidized to give acid forms capable of interference with calcium metabolism. In other words tryptophane may modify the direction of enzyme action, and alter the product, promoting the storage of carbohydrate rather than its further oxidation to acids.

There may be a hormonal relationship. The possibility that tryptophane may be related to hormones has been presented by Sherman.¹⁶ He says, "It has come to be realized that nutritionally essential amino acids may function not merely as 'building stones' but also in more individual and specific ways as precursors of hormones, e.g., a shortage of cystine or lysine results in suspension of growth with surprisingly little, if any, injury; whereas an animal subjected to a correspondingly drastic shortage of tryptophane not only stops growing but soon shows signs of torpidity, lack of tone, or actual illness."

Since it is known that vitamins are often the prosthetic or carrying group for enzyme systems while their specificity may be due to a protein group, we may have a glimmer here of an interesting interrelationship.

Whatever the final explanation of the action of tryptophane in starch metabolism may be, it is interesting to note accumulating evidence which indicates, as does our work with tryptophane, that dental caries is a systemic manifestation:

1. The complex, specialized cell structure of the tooth is subject to many physiological changes.

2. Carious lesions may follow systemic infections. (We have some preliminary evidence of amylase changes following certain of the communicable diseases.)

3. Hypoplasia may be due to disturbance during pregnancy and early childhood.¹⁷

4. Dietary effect on the rate of dental caries.

5. Interruption in enamel formation upon parathyroidectomy.¹⁸

6. Decrease in caries rate during food rationing of war period in Scandanavia, Holland and England.¹⁹

In the course of microscopic examination of crystalline materials from the acid hydrolysis of saliva, it was interesting to observe an abundance of tyrosine. This microscopic finding was readily confirmed chemically with Millon's reagent. We speak of the presence of tyrosine and the possible presence of di-iodo-tyrosine because in it may lie an explanation of fluoride's well known amylase inhibitory effect.²⁰ Tyrosine being an hydroxy-phenyl molecule is subject to ready substitution by the halogens. The routine order of halogen substitution from lowest to highest you will recall as I, Br, Cl, F. Since fluoride forms more stable complexes than do the other halides, we might find here an explanation of its amylase inhibitory power.

SUMMARY

Before closing, we should perhaps summarize the data showing a relationship between tryptophane and caries.

We have found significant and consistent differences in the ways in which caries-associated saliva and non-caries-associated saliva act upon starch. The former contains little tryptophane. It is more oxidative and produces a large amount of acid with starch but only a small amount of reducing substances. The latter contains appreciable amounts of tryptophane. It is more reductive and produces little acid but large amounts of reducing substances.

The ingestion of tryptophane changes the caries-associated type of saliva so that it is similar to the non-caries-associated saliva in the characteristics mentioned. Such changes were noted, following the ingestion of tryptophane, by the small group of the pilot study, namely:

1. Lessening of acid production from starch by saliva in a 2 hour period at room temperature.
2. Increased production of reducing substance under like conditions.
3. Hastened decolorization of preformed starch blue.
4. Lengthened dextrinizing time.
5. An apparent reduction in the caries rate, which finding, however, was with too small a group to be statistically significant.

It is believed that tryptophane, as part of a larger molecule, may function here to condense with aldehydes during starch degradation, thus lessening acid production out of starch and possibly leading to less interference with calcium metabolism both locally and systemically.

NOTE: We acknowledge with gratitude the medical supervision of the Pioneer Group by Dr. Pricilla White.

Hospital-Health Center Programs in Latin America*

RICHARD J. PLUNKETT, M.D., M.P.H.

*Director, Health and Sanitation Division, The Institute of Inter-American Affairs,
Washington, D. C.†*

LATIN America has a distinguished medical heritage that only recently has begun to be appreciated in the United States. With a history of the earliest hospitals in the Western Hemisphere, the southern republics are today participating in a strong modernization movement resulting in some of the finest hospitals and health centers in the world.

Fully 160 years before the first hospital in our colonies opened on Long Island, N. Y., Latin America had many institutions for the care of the sick. It is believed that the first hospital in the Western Hemisphere was the San Nicolas, built in Santo Domingo before 1503.¹ It had 2 stories, and in addition to the main ward, small wards for consumptives and prostitutes. Its personnel included 1 medical director, 1 manager, 1 intern, 6 servants, and 1 chaplain. Other hospitals in the Dominican Republic, Cuba, Puerto Rico, and Panama preceded the oldest hospital at present functioning in the Americas, the Jesus Nazereno, which was founded in Mexico City by Cortez about 1523. Cortez also provided a hospital for skin cases such as leprosy and carate, and Mexico had the first American asylum for the insane, organized in about 1566. The early con-

quistadores everywhere took prompt action in providing hospitals. Royal decrees urged opening of hospitals, asylums, and homes in the new world and these were established both by government representatives and by religious orders. Funds for construction and operation were supplied by Ferdinand and Isabella and the Hapsburg monarchs.

Almost from the beginning there was a tendency to have separate institutions for the different races, and even sexes and professions, such as sailors, soldiers, priests, etc. It was only following self-government in these countries that the segregation of the various races in hospitals of their own ceased. It is still true, however, that a great variety of different kinds of hospitals exists in all of the countries. It is usual to find, in addition to general services, hospitals for tuberculosis, mental diseases, leprosy, infectious diseases, skin diseases, venereal diseases, malaria, cancer, heart diseases, maternity, surgery, and orthopedics. There are many institutions for only men, women, children, armed forces, civil servants, police, social insurance members, or industrial groups.

The existence of early hospitals was generally precarious and they suffered from lack of personnel and equipment. They were generally supported by legacies, lotteries, taxes, and, more recently, government appropriations. In contrast to the situation in the United States where hospitals are largely pri-

Washington, D. C.†*

LATIN America has a distinguished medical heritage that only recently has begun to be appreciated in the United States. With a history of the earliest hospitals in the Western Hemisphere, the southern republics are today participating in a strong modernization movement resulting in some of the finest hospitals and health centers in the world.

Fully 160 years before the first hospital in our colonies opened on Long Island, N. Y., Latin America had many institutions for the care of the sick. It is believed that the first hospital in the Western Hemisphere was the San Nicolas, built in Santo Domingo before 1503.¹ It had 2 stories, and in addition to the main ward, small wards for consumptives and prostitutes. Its personnel included 1 medical director, 1 manager, 1 intern, 6 servants, and 1 chaplain. Other hospitals in the Dominican Republic, Cuba, Puerto Rico, and Panama preceded the oldest hospital at present functioning in the Americas, the Jesus Nazereno, which was founded in Mexico City by Cortez about 1523. Cortez also provided a hospital for skin cases such as leprosy and carate, and Mexico had the first American asylum for the insane, organized in about 1566. The early con-

quistadores everywhere took prompt action in providing hospitals. Royal decrees urged opening of hospitals, asylums, and homes in the new world and these were established both by government representatives and by religious orders. Funds for construction and operation were supplied by Ferdinand and Isabella and the Hapsburg monarchs.

Almost from the beginning there was a tendency to have separate institutions for the different races, and even sexes and professions, such as sailors, soldiers, priests, etc. It was only following self-government in these countries that the segregation of the various races in hospitals of their own ceased. It is still true, however, that a great variety of different kinds of hospitals exists in all of the countries. It is usual to find, in addition to general services, hospitals for tuberculosis, mental diseases, leprosy, infectious diseases, skin diseases, venereal diseases, malaria, cancer, heart diseases, maternity, surgery, and orthopedics. There are many institutions for only men, women, children, armed forces, civil servants, police, social insurance members, or industrial groups.

The existence of early hospitals was generally precarious and they suffered from lack of personnel and equipment. They were generally supported by legacies, lotteries, taxes, and, more recently, government appropriations. In contrast to the situation in the United States where hospitals are largely pri-

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

† Now Associate Editor, *The Journal of the American Medical Association*.

vately managed and supported, hospitals in Latin America are now mainly governmental (national, state, or municipal) institutions, often largely financed by lotteries. Treatment is nearly always free. Since the end of the 19th century there have been rapid strides in modernization and all of the Latin American countries are today increasing the numbers of hospitals and beds and providing up-to-date equipment.

The hospital and health center unit is ideally suited to the extension of health services through the other American republics because of the need for decentralization which exists in many areas. Health services usually stem from the federal level and are frequently concentrated in the large cities. Dissemination of health knowledge and preventive work is not as frequently the responsibility of state, county, and local organization as is the case in the United States. The problems of both curative and preventive medicine in Latin America include all of those of the United States and are further complicated by certain rather typical factors. While the low salary scale for health workers is characteristic of the United States as well, the ubiquity of the part-time health worker is far greater in the southern countries. Where health centers are established, the case loads are high for they commonly serve at least 90 per cent of the population in the surrounding area.

The chief causes of death in Latin America as a whole are tuberculosis, diarrhea and enteritis, heart diseases, the pneumonias, and cancer, although in certain areas malaria and intestinal parasites head the list.² Disease problems include all those of the United States with tuberculosis and malaria frequently assuming epidemic proportions. In addition there are exotic diseases such as typhus fever, plague, yaws, schistosomiasis, filariasis, pinta, onchocerciasis, Chagas's disease, bartonellosis,

leishmaniasis, and yellow fever. Among diseases common in the United States, malaria, intestinal parasites, the dysenteries, venereal diseases, smallpox, tuberculosis, and typhoid fever, as well as malnutrition, appear to be far more prevalent in many areas of Latin America than in any part of this country. For example, the report of the Minister of Health of one country states that malaria is prevalent in 80 per cent of the country; 98 per cent to 100 per cent of the population suffer from intestinal parasites, and 90 per cent of the people suffer from malnutrition. In another country, tuberculosis death rates exceeding 700 per 100,000 population have been reported.

The high prevalence of fatal and debilitating disease inhibits industrial expansion in many regions. To promote health and efficiency throughout the hemisphere international agreements have been executed between the United States and each of 18 of the other American republics for a coöperative health and sanitation program. The United States supplies funds and personnel through the Institute of Inter-American Affairs, an agency of the Department of State. The participating Latin American countries provide personnel, materials, services, and in some instances, as much as 10 times the amount of funds assigned by the United States for operations within that country. Over 1,700 projects have been carried out, including training of health workers locally and in the United States; health education; sanitation, including water supplies, sewage disposal, and malaria control; and provision of improved health facilities and services through health centers, hospitals, laboratories, nursing schools, etc.³

In Chimbote, Peru, which has one of the finest harbors on the West Coast and promise of a great industrial future, the Peru-United States Cooperative Health Service has built and operated a

hospital-health-center unit, staffed by personnel trained and supervised by United States doctors, nurses, and sanitary engineers.

To existing hospitals in 4 major cities of Paraguay, the Paraguay-United States Cooperative Health Service attached health centers, with laboratory, pharmacy, and x-ray facilities for joint use of the hospital and health center. Plans were developed with advice from the Hospital Facilities Section of the U. S. Public Health Service. These health centers, like others established throughout Latin America, include a records and statistical section, a public health nursing section; headquarters for sanitary inspectors; clinics for control of tuberculosis, skin diseases, venereal diseases, dental hygiene, and maternal and child health; health education; a privy construction program, and a home gardening program.

Guatemala has launched a program for survey and construction of a network which comprises the latest developments for joint action to provide its communities with hospital care, public health measures, and social welfare under one roof.⁴ The ancient Mayas of Guatemala produced a scientific treatment of bone fractures and dislocations. They also treated infections with moldy ground corn meal which, applied to the affected parts, was reported to obtain a satisfactory cure in most cases. This may be considered to be an empirical use of antibiotics.

In this country of amazing inherited medical knowledge, modern scientific ways and means of promoting health are being extended by the government, which has formulated a project for the survey, planning, and construction of a complete hospital network generally known as "The National Hospital Plan." Resolutions of a hospital congress held in Quezaltenango resulted in recommendations to the government of the republic to include a hospital con-

struction program as a part of a definite government policy. The recommendations call for a type of institution that will offer a combined service of preventive and curative medicine for the various communities. A preliminary survey revealed the need of a construction program of 34 units to add to the existing hospitals which now serve the population of about 3,500,000. Each unit is to house facilities for the care of the sick and injured, a health center and medico-social service. The political division by provinces has been disregarded with reference to the planning of this network and a new map of the republic has been developed comprising sanitary zones according to the density of the population, incidence of disease, climatic conditions, industrial and agricultural development, and communication facilities. Plans have been completed for a type of 30 bed hospital and health center which provides for construction with Guatemalan funds under the supervision of Institute of Inter-American Affairs personnel.

Similar units are now being built in the towns of La Union⁵ and Santiago De Maria⁶ in El Salvador. Salvadoran authorities are now in agreement in favor of combining small hospitals and health centers. It is believed that this will reduce construction costs, costs of administration of 2 buildings and organizations, and eliminate the necessity of duplicating much equipment and many services such as laboratories and x-rays. Several closely related functions of the outpatient department of the hospitals and of the health center can be combined. This is particularly true of the diagnosis and ambulatory treatment of tuberculosis and venereal diseases, and of the operation of prenatal and post-partum clinics and well and sick child clinics. Similar units are being planned for the many other countries, including Brazil, Chile, Honduras, Mexico, and Peru.

In conclusion it may be said that the organizational and administrative hospital and health center problems of Latin America are basically similar to those of the United States. The provision of adequate service is more frequently hindered in the southern countries by the extensive use of part-time personnel; by the shortage of nurses; by the tremendous case loads; and by the high prevalence of many diseases, both fatal and debilitating. For almost 4 centuries public moneys have been spent in these countries to build and support hospitals and outpatient clinics for treating the sick. It may be said that, comparatively, only very recently has there been governmental responsibility for prevention of disease. This is in contrast to the pattern of appropriation of public funds in the United States which were generally used more for the prevention and control of disease than for treatment.

In Latin America today there is a strong trend toward attacking health problems by prevention. In the United

States there is growing recognition of the need of public funds for establishing hospitals. Consequently from approaches which may be considered diametrically opposite, the United States and Latin America have come to recognize a possible solution in a hospital and health center combination to serve as headquarters for both curative and preventive services for the community.

Transfer of Annual Census of Patients in Mental Institutions

The Bureau of the Census of the U. S. Department of Commerce has made an annual census of patients in mental institutions, since 1926, through its Institutional Statistics Unit. Recently, Federal Security Administrator Oscar Ewing announced the transfer

of this function to the Mental Hygiene Division of the U. S. Public Health Service. It will be carried on in an Institutional Statistics Unit in charge of Dr. Henry D. Sheldon who was in charge of the work in the Bureau of the Census.

The Pattern of Industrial Hygiene in the United States*

WILLIAM T. INGRAM, M.P.H., F.A.P.H.A.

Engineering Field Associate, American Public Health Association, New York, N. Y.

INDUSTRIAL hygiene is a term which has expanded in meaning during several years of rapid development. Perhaps it is now outmoded when applied to one specialized program offered by public health agencies. Industrial hygiene is rapidly becoming one of the functions of general good health practice which must be integrated with several other health functions in order to affect the health and well-being of that segment of population with which it purports to deal.

Today 400 professional persons in 58 state, territorial, or municipal health departments are engaged specifically in preventing disease and protecting the health of a labor force approximating 60 million persons. If consideration is given to the obvious in health practice (a focus of professional eyes on the health of the adult and the improvement of his living and working environment) then the number of professional personnel thus engaged must be increased manifold. On this basis those working on preventable diseases and environmental sanitation contribute something worth while to the health of the worker, *per se*, as well as to his or her family. Thus, one might say that all health agencies are participants in a program of adult health. Such an approach establishes a segmentation of health work by age groups for directed emphasis. Then the practices employed are those ap-

plicable in accordance with the nature of the adult health problems arising in any community, group of communities, state, or nation.

Eight years ago, W. Scott Johnson¹ stated that it was essential to decide two points before the administrator could intelligently propose a program: (1) What does industrial hygiene include? (2) What is the nature and extent of the industrial hygiene problem? Mr. Johnson made no serious error when he answered the first question by saying that the preservation of the health and welfare of the worker in its broadest sense was rapidly being accepted as the scope of industrial hygiene. Certainly today, this thesis has wide acceptance.

ADMINISTRATIVE PATTERNS

There is a third question which Mr. Johnson discussed, namely: How can a state health department bring to all the employed the benefits of proven means of prevention and control of disease and sickness on a state-wide basis? That question has no single answer and still poses a vexing administrative problem.

Why is there no one pattern which places industrial health service administratively? Variations in state laws have a material bearing on the situation. Time and method of the origin of the working division are factors. Attitude of those in policy-forming positions in state government is very important. Immediate objectives of the program are variable. Personnel shortages affect

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

the placement of the unit. Salary scales may introduce limitations on securing and holding competent personnel. Until these and other such factors are resolved, there will always be variability.

In addition, there are some undesirable factors such as personal, inter-bureau, or inter-departmental jealousies which compete with sound planning. These elements are destructive to the program and should be approached decisively and objectively to obtain a meeting of minds. There are notable examples of states in which coöperative effort between persons, bureaus, and departments has resulted in a commendable effort to the advantage of all concerned.

There seems to be little divergence of opinion as to the professional interests which are needed to carry out the details of an industrial hygiene program. These are physicians, engineers, chemists, nurses, sanitarians, and medical, chemical, and biological technicians. But there are differences of opinion as to who should do what. Major patterns appear in the several states with minor variations.

Pattern One:

The separate unit has a director who may be either physician, engineer, or chemist. Functional responsibility divides the unit work into medical and engineering sections. The physician handles medical and clinical investigations of occupational disease, and serves as a liaison between industry and the various services offered as a part of the general preventive medical services of the state department of health.

The engineer handles all contacts dealing with the environmental control of industrial hazards, conducts field studies, and collects samples as needed. The engineer serves as a liaison between industry and the various services offered as a part of the general environmental control programs of the state health department.

The laboratory is separate from other state laboratories and is devoted exclusively to the medical, biological, and chemical laboratory needs of the unit. Administratively the laboratory is responsible to the director, but

functionally may be used directly by the engineer for engineering investigations, and by the physician for medical laboratory work.

Nursing consultation is carried on under general supervision of the director with as much coördination as possible with the engineering interests of the unit.

Units following this pattern have operated during the war and even now without the medical director, or with nominal medical direction furnished by a physician on the staff of the health department. The unit under this pattern comes under the administrative direction of the state health officer.

Pattern Two:

This unit pattern is essentially the same as that of Pattern One with these exceptions. The engineer may or may not be an assistant director of the unit. The unit is placed under the general direction of a bureau or section of preventable diseases, or may be in a department other than the health department. Nursing consultation may or may not be directly under the unit director. There may or may not be liaison with industry through the unit physician or engineer.

Pattern Three:

The unit is not separate but is a division of the bureau or section of environmental sanitation. The engineer is the administrative head of the unit, and the physician either may be in an assistant director capacity, responsible only for functional work of a medical nature, or may be in some medical section and have a consultative relationship to the unit. The laboratory is more apt to be a part of the public health laboratory service of the state department but may be combined with sanitary laboratory service handling water, milk, or food. Nursing services are provided directly in the unit, although the nursing staff may be technically responsible to the nursing supervisor.

Pattern Four:

This type of unit is unique and, depending on the point of view, reflects what may be considered as compromise, coördination of effort, or the outcome of irreconcilable attitudes on the part of individuals, bureaus, or departments.

It may be a separate unit or established under medical or engineering administration. The director may be either physician or engineer. Then functional activities are carried on by physicians, engineers, and nurses who possibly work in the same office, but may be respon-

sible for their actions to their respective professional heads. The laboratory is a part of the department laboratory service. Occasionally other health services, such as dentistry, have assigned consultants to work with industrial populations. In at least one instance the engineer is employed by the Industrial Accident Commission and works with the industrial hygiene unit of the state health department.

The four patterns are all recognizable in the state industrial hygiene services. It is true that they may not be functioning fully according to pattern. Personnel shortages have made it impossible to fill several of the medical positions, and nursing positions. There is a distinct lack of industrial hygiene engineering personnel. Fortunately, these shortages are not usually coincident. Where the engineer is lacking the physician has carried on, and more frequently the medical director is lacking, and the engineer carries the program of the unit.

Today there are 38 industrial hygiene units in 34 states which function as separate divisions or bureaus of health departments while two function similarly in labor departments. Ten state units, 3 territorial units and the District of Columbia unit function as a section or service in the division of sanitary engineering. Four state units form a part of a division of preventive medicine or preventable diseases. Seven states have district or branch offices. There is 1 county unit in California. There are 7 city units as follows: 2 in Missouri, and 1 each in California, Michigan, Ohio, Maryland, and New Jersey. Rather than discuss the individual names of states and local units at length, reference is made to the latest published compilation of Governmental Industrial Hygiene Services in State, Local and Territorial Jurisdiction prepared by Victoria M. Trasko, Statistician, Industrial Hygiene Division, U. S. Public Health Service.² There have been funds budgeted for industrial health work in Delaware, Nevada, and

the Virgin Islands as of 1947, but no actual program yet exists. New Mexico has requested an investigation, and a U. S. Public Health Service survey to determine the program is now in progress. Thus, all states have industrial hygiene services in existence, budgeted, or under consideration.

Mention has been made of industrial health services which may be offered specifically by local health departments. It is of further interest to note the services that are being rendered even though no specific unit has been created. According to returns from 236 local units completing the American Public Health Association's *Evaluation Schedule*³ questions relating to industrial health, 224 departments are prepared to offer industrial health consultative services from one source or another. Fifty departments work coöperatively with the state industrial hygiene unit and 15 have their own facilities. One hundred and fifty departments depend on the state health department and 4 on the state department of labor. In 5 departments, industry itself is providing some type of service. Twelve cities reported no service of any sort. Table 1 is presented to show the breakdown according to community population served and source of service.

TRENDS IN SERVICE

It has been mentioned that emphasis has been placed on a complete program of adult health which includes the worker in industry, but does not neglect the fact that he and his family are participants in the overall community health program. Either alone or with coöperation from state units, industrial workers are receiving through local health departments not only protection from diseases peculiar to their occupation, but are being used as focal points to improve case finding for tuberculosis, venereal disease, and other diseases which are community problems. Nurs-

ing services, too, in factory and home are coördinated in some instances. Health education services are reaching into industry on matters of community interest as well as those of the occupation itself.

Engineering services, too frequently split between those applying to occupational hazards due to air pollution and those more commonly expressed as community problems, are receiving a more rational approach in several states. It has been difficult in the past to recognize that environmental sanitation in the community and in industry were one and the same thing, subject only to degree of problem and method of approach. The hazard, whether borne by air, water, sewage, or food, might have its effect both in community and industry. The trend now is to recognize the common problems and treat them as such through broader programs of industrial sanitation.

Statistical details regarding the specific character of activities have been prepared by Miss Trasko and it is suggested that the paper "In Industry's Service"² be read if detailed information of this character is desired.

It is interesting to note that environmental control is on the increase (61 per cent of 1946 services), while surveys and consultations on programs of medical care are on the decrease (6 per cent of 1946 services). Nursing services have remained fairly constant (6 per cent of 1946 services).

SPECIFIC PROJECTS

There are a number of interesting, informative, and worth-while projects, specific in character, which have been conceived and carried out by industrial hygiene units throughout the nation. If an attempt were made to review all of these, it would be most boring. However, some of the outstanding examples are recounted to bring the present breadth of industrial health work into better focus.

1. The Tennessee Industrial Hygiene Service has inaugurated a State Industrial Hygiene Conference to promote a medium of expression on the mutual problems of industry in that state. Other states are also fostering the same idea.

2. The Georgia School of Technology has recognized that the complexity of modern plants has created the need for a new branch of engineering work known as industrial engineering.⁴ This field involves the planning, organizing, improving, managing, and operation of the various processes required for the production of all types of manufactured products. Men are now being graduated from Georgia Institute of Technology, whose presence in industry should be conducive to better understandings and discussions of industrial sanitation needs to protect health in both plant and community.

3. Many states, including Texas and Tennessee, are compiling standards for measuring industrial environmental protection. The Texas standards include

drinking water, toilet facilities, washing facilities, eating facilities, allowable safe limits of concentration of certain toxic materials, lighting and ventilation.

4. California and Texas have recently had programs of industrial hygiene training for sanitarians.

5. In Oregon, the Portland Superintendent of Schools, high school teachers, and members of the Division of Industrial Hygiene, Oregon State Board of Health, have combined their thinking to produce a teaching outline of a course in industrial hygiene designed to acquaint high school students with such problems.

6. The Baltimore Health Department is exposing hazards in new industrial buildings by arrangement with the department of public works for review of plans by the Industrial Hygiene Division before approval is granted.⁵

7. The Division of Adult and Industrial Health, New Jersey Department of Health, has been the first to start a state-wide industrial sight conservation program. The project includes visual screening, job analysis for minimum visual requirements, color illumination, eye safety studies, and an educational program.⁶ This unit also has embarked on a program enlisting the coöperation of local health departments. A bulletin, *A Community Industrial Health Survey*, has been prepared and given wide distribution. Supporting survey service was offered industry through its local health department. Many communities have taken advantage of this service and have requested surveys.⁷

8. The Mississippi Industrial Hygiene Division, Board of Health, has launched a coöperative state-wide physical examination program of all workers in coöperation with the State Medical Society. The objectives are: (a) an evaluation of the health status of the individual workers of the state, (b) determination of the extent of occupational diseases among the employed popula-

tion, and (c) case finding of tuberculosis, venereal diseases, and cancer.⁸

9. The Division of Industrial Hygiene, Indiana Board of Health, has a medical service program for all state health department employees.⁹ This is an actual service to the employees and serves as a laboratory for the division to try out various reporting forms and other ideas for the organization of plant medical service.

10. North Dakota has given special attention to a determination of health hazards to which agricultural workers may be exposed. Preliminary surveys are being made in coöperation with district health departments.

DISCUSSION

The writer has had occasion in the last 8 months to visit or correspond with state and local health department representatives and with officers of the U. S. Public Health Service. These contacts have led naturally to some opinions on the part of the writer which are based on what was seen, heard, and read. They are set forth here with no idea of criticism, but rather to stimulate the constructive and objective thinking on administrative lines which is so necessary to the establishment of sound approaches and planning.

1. There are wide variations between states regarding the philosophy of approach to industrial hygiene administration. The patterns mentioned are compounded into certain essential common points from which departures are made to meet some localized situation, viewpoint, philosophy, or law.

2. Not one of the patterns appears to be so superior that others should be abandoned in its favor without serious thought.

3. There does not appear to be any valid argument by which one might say that the unit director must be a physician or must be an engineer. Both, by virtue of their professional backgrounds

in public health, are qualified for directive responsibility and both have demonstrated administrative ability in practice. The differences appear to lie in other elements such as mental and personal characteristics.

4. The predominance of functional work appears to be in matters pertaining to environmental control.

5. There are examples of situations in which it appears that full health department liaison is not all that it should be. Neither the medical man nor the engineer can reach his objectives alone, nor can either prevent other operative sections of a health department from pursuing activities requiring industrial contact. For instance, the physician should be on such terms with other departmental medical interests that the tuberculosis case finding program of the bureau or section of preventable diseases is coordinated with the industrial health program rather than being in competition with it.

The engineers in industrial hygiene and environmental sanitation must be so closely tied together that an industrial cross connection survey or a food sanitation program can be carried on without internal bickering and without duplication of effort or complete omission of essential service. The successful industrial hygiene service cannot become a small health department within a health department. Good administrators have recognized this point and are conscientiously striving to prevent its occurrence.

6. There are some dangers in the de-emphasis of industrial health sections. Certainly in all state departments a section on industrial health is desirable whether it be alone or placed under one of the main administrative branches. In the smaller local health units it is a moot question whether or not the work should be assigned specifically, as long as the services are rendered.

7. State industrial health services

have developed and expanded statewide. However, state units can and should make more use of local health departments in gathering basic control information. Perhaps the local departments cannot afford the luxury of technical field and laboratory equipment, but the problems of industry can become far better known and dealt with if local participation and interest are encouraged.

8. Salaries for all professions engaged in industrial health work are below those which will attract and hold responsible and well trained personnel. It is a rarity where salaries are adequate for all professions in the same unit. As an indication of these salary levels 6 medical director positions in widely separated states average a monthly salary range of \$474 to \$584. The minimum entrance salary of the 6 is \$420 and the maximum \$500. Nine top engineering positions selected at random average a monthly salary range of \$339 to \$426, while the minimum and maximum entering salaries are \$250 and \$420, respectively. Similarly, 5 chemist positions chosen at random indicated an average monthly range of \$259 to \$321, and the minimum and maximum entrance salaries were \$185 and \$330. It is difficult to justify these salary levels for such positions of responsibility. It is little wonder that industrial hygiene positions are vacated and go unfilled month after month.

9. In spite of what may seem to be a number of obstacles, there is evidence that better industrial hygiene and adult health programs are being developed in more health departments throughout the country. Contributions of clear thinking and objective action have been and will continue to be valuable.

Let each marshal his health forces and converge on his problems with the administrative pattern best suited to his needs. But let him be sure that it is satisfactory from all points of view,

practical from a working standpoint, and efficient in effecting gains for community and industrial health.

ACKNOWLEDGMENT—The writer is appreciative of the coöperation of the Chief and Staff of the Division of Industrial Hygiene, U. S. Public Health Service, in making numerous data and other information collected by the Division available for review and use.

A State-wide Survey of Typhus Fever in Florida*

E. R. RICKARD, M.D., M.P.H., AND E. G. RILEY, M.D., PH.D.

*Director, Typhus Fever Studies in Florida; State Epidemiologist,
State Board of Health, Jacksonville, Fla.*

DURING the past decade the incidence of murine typhus fever has increased in the United States, until in 1944 a total of 5,338 cases was reported to the various state health departments. It is likely that 1944 was a peak epidemiological year, as the number of reported cases dropped off slightly to 5,167 in 1945 and more markedly to 3,367 in 1946. While it is possible that the increased number of cases reported in recent years may be due in part to better recognition of the disease by clinicians, and in spite of the recent epidemic recession, murine typhus fever still may be classified as an important major preventable disease in the southern United States.

Various investigators,¹⁻⁴ have reported that murine typhus is essentially a disease of the most southerly states and of the southernmost portion of these states. An exception to this observation has been noted in the State of Florida where although considerable typhus has been reported, principally in the 4 major cities of the state, the disease did not seem to have had the same widespread prevalence as in the neighboring states immediately to the north.

Accurate knowledge of the true incidence of any preventable disease⁵ as well as knowledge of the circumstances under which the disease is contracted

are almost indispensable starting points in the orientation of measures aimed at combating disease. For this reason the Florida State Board of Health in co-operation with the Rockefeller Foundation has recently completed a state-wide survey of murine typhus fever in which were investigated all possible known or suspected human cases having their onsets during the years 1944, 1945, and 1946.

METHODS EMPLOYED IN THE SURVEY

Following a preliminary reconnaissance of several months by an epidemiologist, typhus or suspected typhus cases were interviewed by trained lay field investigators working under close medical supervision. An average of 3 lay investigators, supervised by 2 physicians, conducted the survey during the period from July, 1946, to July, 1947. The sources of information leading to the cases were as follows:

Officially reported cases

Positive or suspicious Weil-Felix agglutination reports (titer 1:160 or more) from state laboratories

Information obtained in the field such as verbal reports from physicians or families or neighbors of patients; hospital records; and positive or suspicious reports from hospital or private laboratories

Death certificates

Either the patient or some immediate member of the family who was familiar with the circumstances of the illness was interviewed. Standard case history forms were made out for all interviews,

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

in which the following information was obtained: usual personal data to identify and localize the patient; a clinical description of the disease with notes on onset, fever and subjective symptoms, type of rash if present, duration of illness, and more important laboratory findings. Information was also obtained concerning the possible source of infection with notes on places frequented, trips taken, and exposure to rats or fleas during the 3 weeks prior to the onset of illness. Investigators questioned the patient or family as to the presence of rats at the home, place of work, and places frequented, and in most instances personally inspected the place where infection most probably occurred in order to record their own opinion of the apparent degree of rat infestation. At the close of each interview the investigator made note as to his opinion of the probable place of infection.

In all instances diagnostic classification of the case was determined by the medical directors of the survey after consideration of available clinical and laboratory data. Cases obviously not typhus, or in which other diagnoses seemed reasonably certain, were excluded from the series as were cases with negative serology taken at a time when serology would be expected to be positive. Likewise, cases believed to have been infected outside of the state were not included. The diagnosis of typhus was based on the following 3 principal characteristics of the disease:

Constitutional symptoms including chills, fever, sweats, headache, body pains, and malaise sufficiently severe to confine the patient to bed for a period of at least 10 days.

Typical typhus rash, macular or petechial in character, located on the body or extremities or both and appearing on the second to tenth day of illness.

Weil-Felix agglutination tests. Titers of 1:160 were considered as suggestive of rickettsial infection and titers of 1:320 or more were considered as diagnostic.

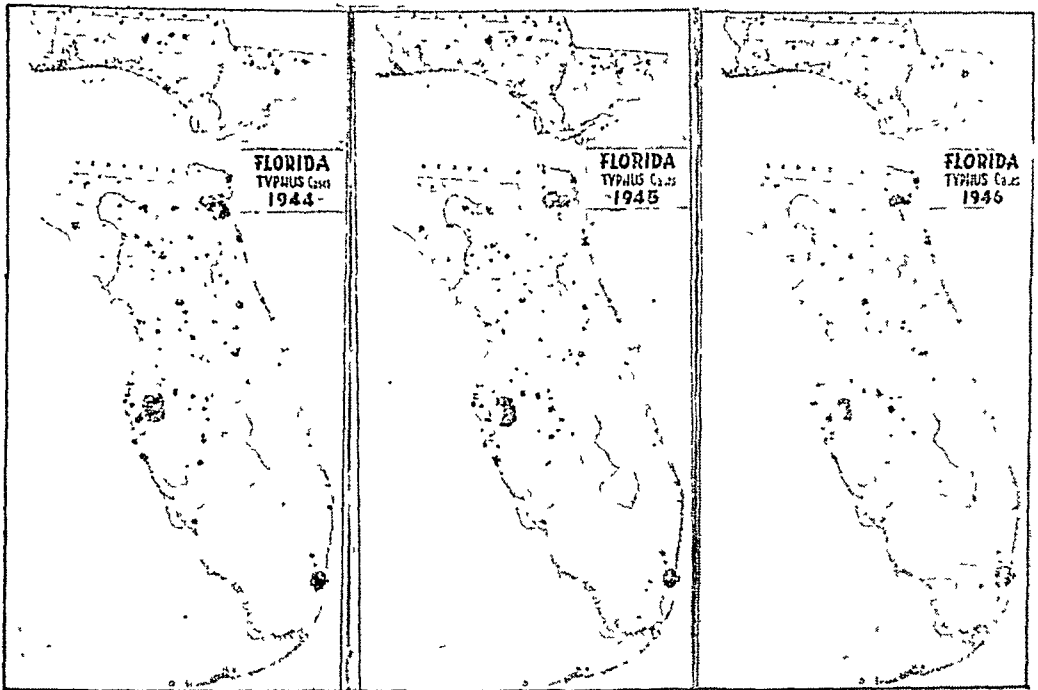

Patients having constitutional symp-

toms, typical rash, and Weil-Felix titers of 1:160 or more; those having constitutional symptoms without rash but with titers of 1:320 or more; and those having constitutional symptoms, typical rash but no serological examination were classified as cases of typhus. Patients with constitutional symptoms, no rash, and titers of only 1:160 and patients with constitutional symptoms only were classified as suspected cases.

Due to the rather extended period of time included in the survey as well as to wartime movement of population, it was not possible to locate a considerable number of persons for interview. Of a total of 3,072 cases or suspected cases 2,055 were interviewed. In calculating the incidence of the disease, cases officially or verbally reported as typhus by physicians and others have been included irrespective of whether they could be reached for interview, as experience revealed that only a small portion of these cases would not be classified as typhus.

A total of 1,337 cases with positive or doubtful Weil-Felix reports from state and private laboratories were investigated in the course of the survey. Of this group of cases 1,038 had titers of 1:320 or more. In correlating clinical and laboratory findings there were 5 per cent of these 1,038 cases in which the diagnosis of typhus was not considered clinically justified. In the cases considered as typhus clinically, the diagnosis was substantiated by the history of a typical typhus rash in 62 per cent of the group, while in 33 per cent there was no history of a rash having been observed. Among a smaller group of 299 cases in which a titer of 1:160 was the maximum observed, 27 per cent were not believed to have had typhus. This percentage was considerably higher than in the previous group; nevertheless, there were 73 per cent of this group who were believed to have had the disease and 44 per cent in which the diag-

MAP 1

nosis was confirmed by the presence of a typical typhus rash. The inclusion of cases with 1:160 titers but which were not investigated epidemiologically, therefore, seemed to lend more accuracy to the series than their exclusion. As the number of these cases was small, it did not greatly affect the various totals and percentages obtained in the survey.

RESULTS OF THE SURVEY

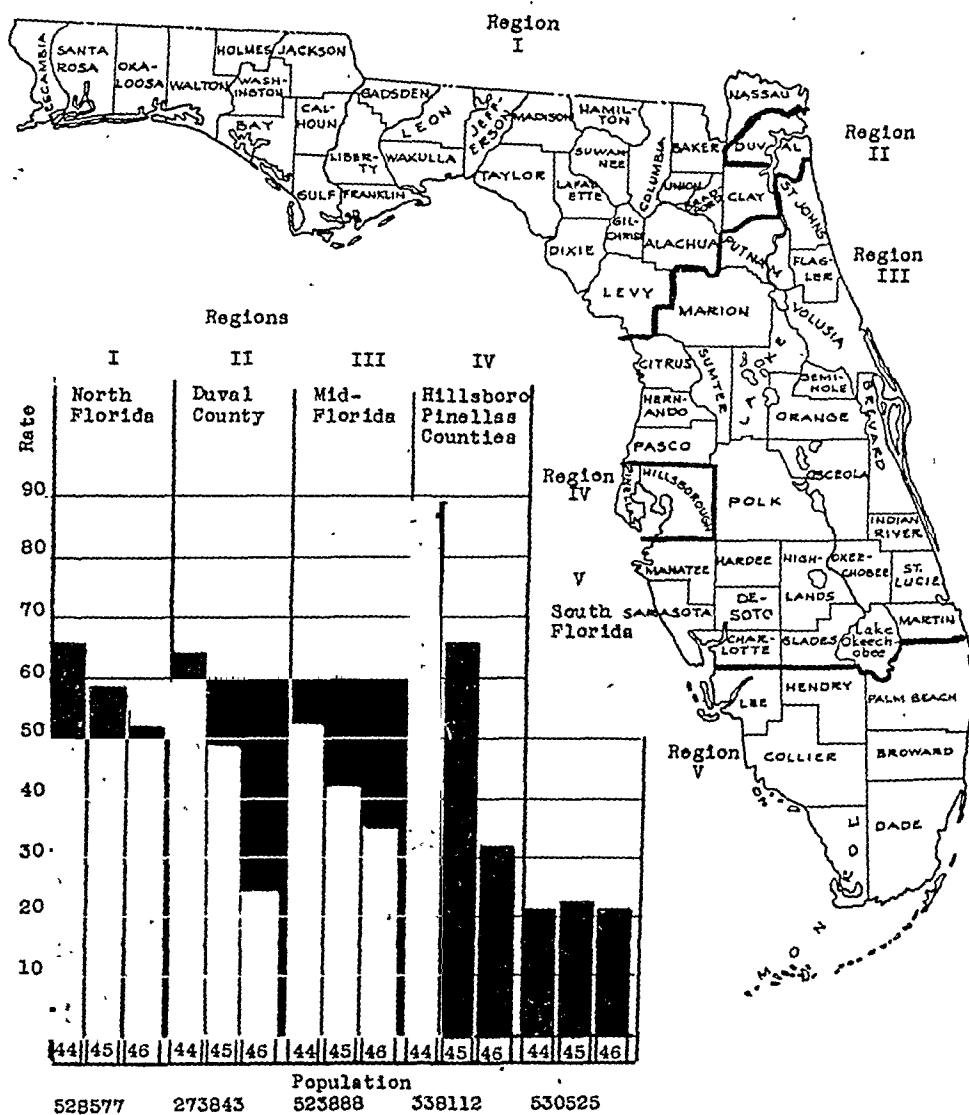

Of the various sources of information leading to the 3,072 cases, official reports to the health departments were the most fruitful; although only 37 per cent of the cases had so been reported. An almost equal number of cases, 34 per cent, were discovered by the investigation of positive or suspicious reports from the state laboratories. The remainder of the cases were found in the field with the exception of a very small number, 1 per cent, found through the investigation of the death certificates of persons who had been reported as dying of typhus but had not been reported as having the disease.

In the distribution of the cases by years there was a definite drop in the number of cases from a total of 1,234 in 1944 to 1,045 in 1945, and 793 in 1946. This trend was in accord with data on officially reported cases for the entire United States, as above quoted, but was at variance with the numbers of previously officially reported cases for the state for these years which were respectively 496, 380, and 420 cases.

On Map I the geographical distribution of the cases for the 3 years has been illustrated. Each dot represents one case which has been localized according to probable place of infection, when such could be determined or if this was not possible according to the place of residence. Little change in geographical distribution from year to year is evident. While it is apparent that cases are grouped in certain localities, there still is a widespread scattering of cases in almost all regions of the state. By and large, the distribution of cases follows almost exactly the distribution of the population.

Chart I
Typhus Fever Yearly Attack Rates per 100000 Population in
Different Regions during 1944, 1945, 1946.

STATE OF FLORIDA

The State of Florida extends through a wide range of latitude and consequently has certain climatic variations in different regions. For this reason the yearly indices of the disease have been analyzed separately for 3 principal regions of the state which have been illustrated on the map contained on Chart I. Northern Florida has essentially a "southern" climate characterized by long hot summers but broken by a

moderate winter season with fairly frequent frosts. Southern Florida has a climate almost tropical in nature with very rare winter frosts. The climate of mid-Florida ranges between those of the northern and southern regions. Throughout the state the winter months are relatively dry while the summer is characterized by high humidity and heavy rainfall. In addition to the above regions, data were also analyzed apart for

Duval County located in northern Florida and for Hillsborough and Pinellas Counties in mid-Florida. In these 3 counties extensive programs of typhus control have been carried out during the period covered by the survey. In the rest of the state control measures have been too limited in scope to have had any appreciable influence upon the incidence of the disease.

A comparison of the yearly attack rates per 100,000 inhabitants for the different regions as illustrated on Chart I reveals that, with the exception of south Florida, the trend of the rates has been somewhat similar. A recession may be noted in the first four regions which is accentuated in Regions II and IV where control measures were carried out. South Florida differs from the remainder of the state in having considerably lower attack rates in which no recession is apparent.

Seasonal curves for Regions I, II, and IV were similar and were characterized by summer peaks occurring in

June or July sometimes followed by secondary peaks in November or December. The disease had its lowest incidence in the late winter or early spring, generally in February or March. In Region III, mid-Florida, secondary peaks were more pronounced while in Region V, south Florida, the cases were more evenly distributed throughout the year.

Of a total of 3,072 cases or suspect cases under investigation for the 3 year period included in the survey, it was possible to complete interviews on 2,055 cases. Of the cases interviewed, 85 per cent were considered as typhus according to the criteria previously established. Thirty-eight per cent had all 3 cardinal characteristics of the disease: severe constitutional symptoms, significantly positive Weil-Felix titers, and typical rash. Seventeen per cent had constitutional symptoms and positive Weil-Felix titers but no history of rash, and 30 per cent had typical clinical findings and rash but were without serological

Chart II

Types of Business Houses in Which Infection was Probably Acquired in Cases Where Source of Infection was Attributed to Business Houses.

| | Number of Cases | Percent 0 10 20 30 40 50 60 70 |

confirmation. Only 15 per cent of the series were classified as suspected typhus in which the diagnosis was believed to be open to question.

In the classification of cases by probable places of infection, cities or towns having a population of 1,000 or more were considered as urban. This division was made in the belief that it would be more useful in planning control measures than the commonly accepted criterion of 2,500 inhabitants. On this basis, of the total population of the state, 2,250,061 persons according to the 1945 census, 1,541,416 or 69 per cent

are urban, and 708,645 or 31 per cent are rural dwellers. Seventy-six per cent of the 2,055 cases investigated were believed to have been contracted in urban and 24 per cent in rural localities. These percentages were reflected in the attack rates per 100,000 for urban and rural populations which were 101 and 70 respectively. There were many reasons to believe, however, that with the methods used in this survey rural cases would more likely have escaped discovery than urban ones and that there was no real difference in these attack rates. In the combined urban and rural cases,

CHART III
Comparative Age, Race and Sex Specific Attack Rates per 100,000 Population
(Based on 2,327 cases occurring in 1944, 1945, and 1946)

67 per cent were believed to have been infected in the homes and 28 per cent at places of business, while in 5 per cent of the cases it was impossible to form an opinion as to the probable place of infection.

On the upper portion of Chart II the ratio of the number of cases whose source of infection was ascribed to food handling and non-food handling business establishments has been illustrated. Here it may be noted that the greater portion of the cases were ascribed to food handling establishments. Of these establishments, groceries and restaurants were found to have been the principal offenders, as 47 per cent of the cases believed infected in business houses were attributed to these 2 types of establishments. To other types of food handling establishments 21 per cent of the cases were attributed. Less than one-third of the cases were traced to non-food handling establishments. In many instances the source of rat infestation responsible for infection in non-food handling establishments was believed to be in nearby food handling business houses.

Indication of the probable place of infection necessarily was a matter of the opinion of the investigators. For this reason an analysis of the occupations of the patients immediately prior to illness, as illustrated in the lower portion of Chart II, should be of interest. Here it may be seen that 53 per cent of the patients had not been employed in business. These patients had occupations the nature of which would keep the individual about home the greater portion of his time. Of those employed in business, 27 per cent of the total number of patients were employed in non-food handling businesses of rather widely diversified natures, and only 22 per cent in food handling establishments. These findings substantiated the opinions of the investigators in ascribing 67 per cent of the source of infection to homes.

In Chart III the age, race, and sex specific attack rates per 100,000 of the population have been illustrated. The low incidence of the disease in the 0-9 age group would seem at direct variance from that which would be expected from a disease which was most frequently contracted at home and suggests that typhus fever may not be recognized as readily in this age group as among older persons. The lower rate in the white male 20-29 age group may be explained by the absence of a large portion of this group in military service during the war years. Attack rates in the colored population were lower than the white in all age groups. This, likewise, was contrary to expectation in the case of household infection of the nature of typhus. The colored population commonly inhabits the older and, therefore, more heavily rat infested residential districts.

DISCUSSION

That murine typhus fever has been and still is an inadequately reported disease is the opinion of many public health workers and has been commented on in the literature.⁵ While it is true that in 15 per cent of the cases investigated in the present survey the diagnosis of typhus fever could not be considered as completely substantiated, there is reason to believe that by the methods employed all frankly typical cases of the disease were not discovered. Nevertheless, the magnitude of the typhus problem in the state has been indicated to be approximately two and one-half times as large as that shown by the number of officially reported cases. Moreover, epidemiological evidence collected in the survey suggests that in young children and in the colored race cases of typhus, perhaps mild and atypical or even subclinical, are escaping diagnostic detection. In consideration of the large number of febrile exanthemata to which young children are sub-

ject, the greater difficulty of the differential diagnosis in this age group is understandable.

In planning programs for the control or eradication of typhus, knowledge not only as to the case incidence but as to the circumstances under which disease is acquired is desirable for the orientation of control measures and subsequent evaluation of results achieved. Ratproofing of buildings has been used extensively as a method of rat and typhus control. In many respects this method is comparable to permanent drainage measures in malaria control. Like permanent drainage, ratproofing has definite economic limitations and, so far, has been applied principally to urban business establishments. The results of the present survey have shown, however, that business establishments are responsible for less than one-fourth of the cases of typhus in the state. Evidence suggested that 67 per cent of all infections were contracted in homes.

In many cities in the United States DDT dust has been applied to rat infested dwellings and buildings particularly in the poorer residential districts, in an attempt to control typhus by the reduction of fleas on rats. Encouraging reports have appeared in the literature both upon the reduction of flea indices⁶ and the reduction of human cases of typhus⁷ by this method. So far, however, little has been reported upon the necessary frequency of application of dusting and the duration of its effect, and the economic practicability of the method over a long period of time has not been evaluated.

The problem of the control of rural typhus would appear to be difficult of solution because of the high costs due to long distances involved. The Florida population is essentially urban, as previously defined, and only one-fourth of the cases were found to be of rural origin. Sporadic cases scattered in

small towns and cities throughout the state may be considered the same as rural cases, however, from the standpoint of the application of control measures. The relative numbers and locations of these cases may be appreciated by an inspection of Map I.

In evaluating any control measure, the natural epidemiological variations of the disease from one year to the next should be considered. Epidemic peaks and recessions have been noted in nearly every known infectious disease. It would seem likely, therefore, that the same natural variations exist in typhus fever. Apparently in the State of Florida, as in other states which have reported considerable numbers of cases, the disease was receding in 1945 and 1946 from an epidemic peak reached in 1944. Control measures applied during these years would, therefore, appear to have considerably accentuated the decline in the number of cases in the localities where applied but may not necessarily have been responsible for the entire decrease in incidence.

SUMMARY

A state-wide survey of murine typhus fever was conducted in Florida in which were investigated cases or suspected cases of this disease having their onset during the years 1944, 1945, and 1946. Sources of information leading to cases were official reports to health departments, state laboratory records, information obtained in the field, and death certificates. For 2,055 of the 3,072 cases under investigation, standard case history forms were made out by trained lay field investigators who endeavored to ascertain the source of infection in every case interviewed.

By the methods employed the incidence of the disease was determined to be approximately two and one-half times that indicated by numbers of previously officially reported cases. Evi-

dence was adduced which suggested that numbers of cases in young children and the colored race were not being recognized as typhus.

The disease was found to be almost proportionately distributed in urban and rural populations but the actual number of cases in urban populations was considerably higher because of the preponderance of urban dwellers in the state. Twenty-eight per cent of the cases were believed to have been infected in business establishments while 67 per cent were believed to have been infected in homes.

Canadian Public Health Association

Vancouver, British Columbia, will be host to the Canadian Public Health Association from May 18 to 20 when the association holds its annual meeting in that city. Hotel Vancouver will be headquarters and the center of the sessions.

The meeting is sponsored by the public health workers of British Columbia with the Washington State Public Health Association as co-hosts. Chairman of the conference will be G. F. Amyot, M.D., Deputy Minister of Health for British Columbia and President of the Canadian Public Health Association. The annual meeting of the Washington State Public Health Association will be held on May 17.

Sectional sessions will be held on Tuesday morning, May 18, with general sessions following on Tuesday afternoon and Wednesday morning. Wednesday afternoon will be reserved for relaxation. The final session, Thursday afternoon, will be a panel discussion under the leadership of Carl E. Buck, Dr.P.H., Resident Lecturer in Public Health Practice, School of Public Health, University of Michigan. The Honorable Paul Martin, Minister of National Health and Welfare, will be the luncheon speaker on Tuesday.

Further information can be obtained from the Division of Health Education, Department of Health, Parliament Buildings, Victoria, B. C., Canada.

Paralytic Shellfish Poisoning on the Canadian Atlantic Coast*

J. GIBBARD, F.A.P.H.A., AND J. NAUBERT

*Laboratory of Hygiene, Department of National Health and Welfare,
Ottawa, Canada*

IN 1936, Canadian public health officials realized that there was a mussel poisoning problem in Canada when there occurred in Nova Scotia 5 cases with 2 deaths following the consumption of mussels. The facts were reported by Dr. P. S. Campbell, Chief Provincial Health Officer for Nova Scotia, and later reported in a technical paper by Murphy.¹ A special *Bulletin* released recently by the Canadian Government authorities² is devoted entirely to the shellfish poisoning problem on the Canadian Atlantic Coast.

One of the earliest references to mussel poisoning is contained in a historical account of Captain Vancouver's expedition entitled "A Voyage to the Discovery of the North Pacific Ocean" published in London in 1798. The reference is to several outbreaks of mussel poisoning with one death among the crew of Captain Vancouver's ship. The incriminated mussels had been collected from an area which is still known as "Poison Cove." The description of the symptoms fits the condition which is now known to be caused by poisonous shellfish. Another interesting reference may be found in the *Washington Exploration Quarterly*, vol. 18, p. 284, in connection with explorations of Alaska by Russians which took place about 1790. In this account, members of a

Russian party are reported to have been affected by poisonous mussels, as follows: "One hundred of his hunters were poisoned by mussels from the Peril Straits and died."

There are no cases of mussel poisoning on record in Canada prior to 1936 except the ones just referred to. However, one notable result of careful inquiries conducted in the maritime provinces in 1945 was the revelation of the fact that there have been many unrecorded outbreaks among human beings and domestic animals. It was also found that residents of fishing communities know from old traditions of the dangers of eating poisonous mussels. They have also known that poisoning is confined to definite localities. They have even acquired food habits that afford a certain degree of protection. They will eat, for instance, only the adductor muscle of the scallops, the rim being considered poisonous. Others eat the "red roe" or "coral" as the ovary is called, and regard all other parts of the rim as unfit for food. Although most appreciate the danger of eating mussels, many are still not convinced that soft-shell clams can be poisonous. The allergic form of mussel poisoning has occasionally added confusion in identifying outbreaks. The evident prevalence of limited and hazy notions on this matter is further confirmed by indefinite reports of cases. Thus, in 1937, 1 case may have occurred at Pocologan, New Brunswick, and there were probably 2 deaths

* Presented at a Joint Session of the Laboratory and Engineering Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

years ago at Hailey's Cove, N. B. There was also another report from this locality in 1936, that probably 3 cases had occurred following the consumption of blue mussels.

Following the Digby outbreaks, some investigations were carried out and the seriousness of the problem was revealed.³ Since 1943 surveys have been conducted without interruption in order to determine the danger season, the dangerous areas, and the dangerous species of shellfish. This was successfully accomplished with the collaboration of the Fisheries Research Board of Canada and the Dominion Department of Fisheries. Sampling programs were drawn up and included all of the commercial clam areas as well as the canning and the shucking plants. The results obtained led to the institution of a quarantine regulation whereby areas showing toxicity increasing above a certain level may be closed immediately to fishing. Under this authority, also, the packs of canning and shucking plants may be subjected to regular or periodic sampling for the detection of mussel poison. These measures have already proved their efficiency. The consumers of clams and other shellfish of the home trade as well as the export market are now assured of a perfectly safe food in all its popular forms. This beneficial result, on the other hand, may be expected to reflect on the Canadian shellfish fishery by guaranteeing a steadily increasing market.

The detection of mussel poison is effected by a simple test which was developed from the "field test" used by Sommer and Meyer.⁴ Briefly the steps are: mincing the washed shellfish meats; suspending a determined portion of the mince in an equal volume of tenth normal hydrochloric acid and boiling gently for 5 minutes. The mixture is made up to the original total volume with distilled water, the pH adjusted to between 4.0 and 4.5, and then centrifuged

or permitted to settle. The clear supernatant liquid is injected intraperitoneally into at least three white mice. The mean death time is referred to a standard toxicity graph from which toxicity is determined and expressed as "mouse units." The mouse unit is the amount of poison, contained in 1 ml. of extract, that kills mice of 20 gm. weight in 15 to 20 minutes.

The quarantine level has been set at 400 mouse units, and was first based upon the work of Sommer and Meyer.⁴ The effectiveness of this level in affording consumers a more than ample degree of protection is now well established. Epidemiological studies carried out in 1945 in the maritime provinces have shown that the mildest symptoms of poisoning may be observed only when a quantity of poison in excess of 1,000 units has been ingested, thus confirming the 400 mouse unit quarantine level.

The epidemiological study referred to above was carried out in 1945 and has been reported in the literature.² An outstanding feature of this study is that case records included the place of origin of the poisonous shellfish as well as the date they were fished. It was thus possible to correlate toxicity of raw shellfish, dosage of poison, and symptoms. The data indicated that the minimum amounts of poison required to produce mild, severe, and extreme symptoms of poisoning in susceptible persons might be in the neighborhood of 2,000, 10,000, and 25,000 mouse units respectively. The clinical picture was carefully studied in the 28 human cases in New Brunswick in 1945. The symptoms, varying in severity with the amount of poison ingested, were consistent; numbness about face and mouth, "pins and needles" feeling about the lips, vomiting, headache, dizziness, difficulty in breathing, general weakness, occasional paralysis. The poisoning of domestic animals, particularly hens and house cats, seems to have been quite

common. More frequent illness among human beings is apparently prevented by the food habits of the people in the fishing communities and their traditional knowledge of the dangers involved. It was also found that there were many who ate toxic shellfish without ill effects. These cases were of particular interest since they indicated a degree of human resistance to the poison. This was found especially among inhabitants of shore communities. Most of the sufferers were among non-residents of these communities such as picnickers, for whom shellfish were not a habitual item of diet.

All of the species of mollusks more or less generally favored in the Bay of Fundy areas have been found toxic to some degree, during the late summer and early fall. These comprise, in decreasing order of toxicity, the red mussel (*Modiola modiolus*), the blue mussel (*Mytilus edulis*), the bar clam (*Macra solidissima*), the razor clam (*Ensis directus*), the scallop (*Placopecten grandis*), and the soft-shell clam (*Mya arenaria*). The last mentioned is the most important commercially and, fortunately, is the least dangerous.

The distribution of the poison within the shellfish was found to vary considerably with the organs. While Pugsley⁵ demonstrated the poison to be centered in the siphon of the butter clams (*Saxidomus*) of the West Coast, the toxicity records of the Atlantic Coast mollusks show that the poison is most concentrated in the liver. The gill is next in importance, and the remaining parts come in third place. The soft-shell clam (*Mya*), however, was shown to undergo a seasonal reversal of conditions, the liver having the highest toxicity level during the summer but ceding its place to the gill during the fall and winter months. Muscle tissue in all species was shown to have a low capacity for the poison; in the case of the scallop, however, there was never any trace

of poison demonstrated in the adductor muscle, a most fortunate circumstance indeed, considering the popularity of this part of the scallop as a delicacy.

With regard to the location of toxic beds within any given area, the toxicity was found to increase from nil to high levels with the proximity to the open sea. This is indeed a boon for the industry since most of the main commercial beds may be left open to fishing with little or no risk. Such is the case in Passamaquoddy Bay, where the inside areas have been consistently free of poison. Farther along the New Brunswick side of the Bay of Fundy, the commercially important areas that are open to the bay itself had the highest toxicity levels. These have been closed to fishing. Many commercial clam areas in Nova Scotia have been demonstrated to be free of poison, and all areas in Prince Edward Island and along the Northumberland Strait have also been found safe.

The ultimate source of the poison has been shown to be in a species of dinoflagellate *Gonyaulax tamarensis*, one of the planktonic organisms on which the shellfish feed. The appearance of high toxicities and large numbers of the dinoflagellate have been simultaneous, that is, between mid-July and the end of September.

Attempts to devise means of destroying the poison were the object of numerous experiments. In that regard, the chief of these were to determine the effects of domestic cooking, shucking, and commercial canning. Domestic cooking experiments included steaming for 15 to 20 minutes in a covered pot with only sufficient water to cover the bottom; boiling in water for 20 minutes; and "pan-frying" for 15 minutes in an open pan with just enough fat to prevent burning. Although these cooking processes were found to reduce the poison content of the raw meat by at least 70 per cent, they were demon-

strated to fall short of providing sufficient protection.

While shucking was demonstrated to have no effect whatever toward reducing the poison content of clams, the process of canning, as it is practised commercially, was found to be quite efficient. Presumably certain factors forming part of the process, such as discarding clam bouillon, the alkaline condition of steaming and the retorting temperature are jointly responsible in reducing a raw meat toxicity of 1,000 mouse units to a safe level. This protection is effectively insured by sampling systematically all commercial packs when the toxicity in clam fishing grounds rises over the quarantine level of 400 mouse units, and releasing these packs for sale only if free of demonstrable poison.

Commercial fishing of mussels of any species from areas in the Bay of Fundy either for canning or for sale as raw food has been prohibited at all seasons since the autumn of 1943, when their toxicity was found to be several times higher than that of clams.

The scallop industry presents no problem since the adductor muscle, the only part marketed, has been demon-

strated to be consistently free of poison.

During the past three years, the Department of Fisheries, on recommendation from the Department of National Health and Welfare, has imposed temporary restrictions on the taking of shellfish from restricted areas. At such times the grounds have been closed to all fishing except for canning. Dangerous areas have been posted with warning signs and patrolled by special wardens at week-ends when picnickers visited them. Beyond this, there is little that can be done to enforce the fishing prohibition on the general public. On the other hand there has been no difficulty in maintaining good control of all commercial operations.

THE WRITTEN WORD

WE take the "Book," and the whole miracle of the written word which is involved, far too lightly.

Each human being, according to his innate capacity, learns something as the days go on. He accumulates experience, to some extent he correlates it and interprets it. He becomes wiser as the years pass. And then he dies; and the complex neural mechanism, developed and refined so laboriously, disintegrates into dust.

In primitive society, something of the gathered wisdom is passed on by word of mouth. Folklore is gathered and sagas are learned by rote; but progress by this means is very slow. The real turning point in human evolution came when some brilliant innovator in a given society conceived the idea of the written symbol; and the way was gradually opened for full transfer of human thought to coming generations. The thinker attained immortality; and the process of real psychological and social evolution was opened to mankind.

So the book is the basic instrument of human progress. There is something almost sacred about an ancient book—or about a modern book which has in it the potency of living so that it may become an ancient book. A hundred feet from the desk on which this editorial is written is one of the oldest printed volumes in the world, the first edition of *The Conciliator* by Peter of Albano, published at Mantua in 1472, and one of the great medical works of all time. Is it not thrilling to realize that these pages which lie under my hand in 1948 have for nearly five hundred years been pored over by scholars, that these beautifully printed words have stimulated in the brains of twenty generations currents of thought which have led us on to new conceptions and new syntheses? The entire fruit of the speculation and of the aspiration of men is embodied in the printed word.

Therefore, this number of the *Journal* is devoted to books; and we are fortunate in having persuaded Huntington Williams to write the Special Review Article which opens the issue, as not only a distinguished health administrator, but also a scholar and a book lover.

As Dr. Williams has said, no two bibliophiles would recommend quite the same books. He mentions only casually what some of us would put at the top of the whole list—the *Report of the Sanitary Commission of Massachusetts* (1850). It is true that the report is so rare that few health officers have even seen it; but it

may be plausibly maintained that this is perhaps the most remarkable single document in the history of public health. You will find in its pages a preview of almost everything we are doing nearly a century later in the field—and of some things which even now remain as challenges of the future. Perhaps the Editor is prejudiced in this regard, since he has the good fortune to own a specially precious copy of the Report in question. It was sent by Lemuel Shattuck, head of the Sanitary Commission, to the Mayor of Providence with a personal letter (pasted in the front of the Report). Years later it was thrown out with other musty tomes on the city dump, rescued by an intelligent citizen and turned over to Dr. C. V. Chapin, then Health Officer of Providence; and presented, with a personal inscription, by Dr. Chapin to the present owner. It is our earnest hope that either the State of Massachusetts or Harvard University (or the American Public Health Association?) may commemorate the Hundredth Anniversary of this great document by reproducing it for the wide distribution which it deserves.

One word more, to the student of "The Health Officer's Bookshelf," and to the readers of the many new volumes reviewed or presented in this issue of the *Journal*. As we garner the treasures of the past, we must not be merely passive beneficiaries. What we gain from the written word should be handed on through the same medium, enriched and enlarged by the mites which all can add to the common store; each of us, one humble link in the long chain of progressing human experience.

A HEALTH DEPARTMENT MEDICAL CARE PROGRAM

THE Maryland Medical Care Program was described in general terms in this *Journal* a year ago.¹ The operation of this plan has been intensively studied by the Subcommittee on Medical Care of the Association, and an important report on the subject will shortly be available for distribution. We are permitted to make reference to the main conclusions of this report.

The Maryland plan was an outgrowth of a movement initiated by the Medical and Chirurgical Faculty (the State Medical Society of Maryland) and was formulated after careful study by the State Planning Commission. It aims to provide medical, hospital, nursing, and dental care for the indigent and the "medically indigent" of the state. It is directed by the State Health Department, with the advice of a State council on Medical Care representing state health and welfare agencies and the various health professions concerned.

The provision of hospital service remains in the hands of local welfare departments; and shortage of funds has so far limited the program largely to home and office physicians' calls and certain prescribed drugs. It has not made much progress in the care of the "medically indigent" for whom special authorization for each specific illness under a means test is required. For recipients of public assistance in any form, however, registration for service is automatic; and this group of the population has—for the first time in the United States—received basic physicians' services under a state-wide system operated by a state department of health. The experiment, therefore, deserves careful study.

Our Subcommittee on Medical Care has criticisms of the present program and has pointed out a number of desirable changes (many of which are advocated by the Maryland Department itself). On the whole, however, it is found that "after original apprehension about the flood of demands for free medical care and the burdensome volume of 'red tape' proved groundless, county health officials found

the new program relatively easy to administer, the wide relationships with professional people helpful, and the opportunities for service augmented." The program is a decentralized one and is administered on the local level by county health officers, each with his own advisory committee. Our subcommittee finds that lack of local initiative (or existence of local prejudice) has caused some areas to lag behind; but the decentralized plan offers valuable assurance against the bog of "bureaucracy." Our subcommittee finds that the Bureau of Medical Service of the State Department of Health "has demonstrated a high level of administrative and professional efficiency in the development of the Maryland Medical Care Program." Actual service is sought by each recipient from the physician of his own choice and payment is made directly to the physician by the State Treasurer. "Physicians and dentists feel that the program has been skilfully organized to involve a minimum of 'red tape' in administration. They are required each month to submit a single standard form for every patient seen. The forms are compactly designed to reduce paper work."

The Maryland program has not yet found all the answers; but it is a serious attempt to solve a problem which has troubled all who are seriously concerned about the public welfare; and which cannot be solved by arm-chair pronouncements but only by trial and error.

The Board of Trustees of the American Medical Association, in a recent statement wipes this problem comfortably off the slate.² It states that the group of the population "who are wholly dependent on the public welfare for even their housing, clothing, and food . . . is well cared for on a charity basis in most areas, but certain arrangements must be made in a few areas. The problem here is a social one of raising the economic level of the group rather than a medical one." It is difficult to take refuge behind the Utopian ideal that a class below the poverty line can be completely abolished—unless one is a Marxian idealist of the most extreme type. Nor can it be maintained with any seriousness that this group of the population "is well cared for on a charity basis in most areas." All scientific studies of the question have shown beyond any shadow of doubt that this low economic group has less than half the medical care which is essential for health and which is enjoyed by the well-to-do. Even if hospital and clinic facilities were actually reaching the lower economic group in sufficient quantity, we should hardly be satisfied. The public health worker realizes that personal individual contact with a family physician of one's own choice is essential to good medical care. Such a relationship is completely absent from most "charity medicine"; but is clearly visualized in the Maryland plan.

Equally unfortunate—and wholly unjustified—is the thesis maintained by the Board of Trustees that "Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of service rendered"; and also, their "emphasis on the principle that medical care and treatment are not properly functions of public health units." We challenge the ability of the Trustees to provide any concrete evidence in support of the assumption that health department direction of medical facilities tends to deterioration in quality of service. The high standing of tuberculosis sanatoria chiefly under health department direction is a fairly clear refutation of the assumption.

Since it is agreed that funds for the care of the indigent must chiefly come from the public treasury, it is obvious that some form of control of these expenditures must be provided. The practical alternative is a choice between welfare

departments and health departments. It might have been assumed that the American Medical Association would have preferred medical rather than lay control of medical care allotments. That at any rate is the position of the American Public Health Association which recognizes that the health officer as representative both of the medical profession and of the public interest is the man to do the job. That is why the Association³ has declared in its resolution on "Medical Care in a National Health Program" that "A single responsible agency is a fundamental requisite to effective administration at all levels—federal, state, and local. The public health agencies—federal, state, and local—should carry major responsibilities in administering the health services of the future. Because of administrative experience and accustomed responsibility for a public trust, they are uniquely fitted among public agencies to assume larger responsibilities and to discharge their duties to the public with integrity and skill."

Of particular significance is the progress already made in Maryland in the basic improvement of the quality of medical care. "Plans have been completed and the necessary funds have been appropriated for the extension of diagnostic facilities by expanding the staff and equipment of the eleven branch state laboratories in order to make it possible for them to provide an increased volume and variety of clinical laboratory procedures."

"Additional public health nurses have been added to the staff of a number of county health departments. A study is being planned in one county in order to determine the requirements of patients under the medical care program for bedside and other nursing services. In addition, a detailed clinical study of the dental needs of one hundred eligible patients has been completed in one county and others are contemplated. Once these estimates of need are available, it will be possible to formulate more appropriate programs of service."

"Probably the most important potential contribution of the medical care program in improving quality is the projected plan for consultation services. This plan calls for an organized consultation service based on the facilities and personnel of the medical schools in Baltimore, whereby specialists would go into the counties at regular intervals and hold consultations with local practitioners on difficult cases under the medical care program."

It is such comprehensive planning for improvement in basic medical services and for their correlation with preventive services that can be attained—and can only be attained—by health department leadership. The Maryland plan is only a beginning; but it is a most important beginning. It reflects great credit on the Maryland State Department of Health; and on the Medical and Chirurgical Faculty which stimulated the movement nine years ago. It is a program which should be seriously studied and its lessons applied in other states.

ADMINISTRATIVE JUDGMENT IN THE CONTROL OF TUBERCULOSIS

TWO articles on tuberculosis in this issue of the *Journal* present stimulating differences of opinion in regard to what should be our major emphasis in the detection and control of this disease. F. J. Weber and R. J. Anderson stress the

value of community-wide x-ray programs (envisioned for 92 of the largest cities of the United States). They advocate such surveys in densely populated areas as "an expedient means for the elimination of infectious foci"; as important factors in health education; and as a stimulus to the development and utilization of clinic and sanatorium facilities.

Dr. J. Arthur Myers, of the University of Minnesota presents a somewhat different program based on experience, particularly in the rural areas of his state. His aim is not the "control" of tuberculosis, but its "eradication." He points out that the incidence of clinical tuberculosis is so low in Minnesota that an epidemiological attack on the disease based on clinical cases could accomplish only meager results. A campaign to combat the disease by x-raying he compares to the use of "a fish sieve with meshes which prevent only those of ten pounds or more from passing through." He points out that only 75 per cent of the lung area is visualized in this procedure and that only relatively gross lesions are revealed. It is the tuberculin reactor who should be the keystone of our program, in Dr. Myers's view. In essence, every reactor is a case of tuberculosis in a mild form; and he quotes Bogen to the effect that about half of all infected persons ultimately develop clinical disease. Close and continued observation of all reactors is, then, the only sound procedure; and this need not be an unduly arduous task, since less than 10 per cent of the children under 18 years of age are found to react in many areas of Minnesota. Even in Minneapolis, the reaction rate at high school age is only 12.5 per cent; and the annual infection attack rate, only 0.33 per cent. Not unnaturally, Dr. Myers is strongly opposed to the use of BCG, since its general application would mask his favorite test.

When good men disagree there is usually some sound reason for their disagreement. We suspect that, in the campaign against tuberculosis, tactics may wisely and properly be varied in relation to local conditions, and particularly with respect to the stage of progress which that campaign has already reached.

In areas where the incidence of tuberculosis is very high and clinic and sanatorium and nursing facilities are inadequate (or in special groups such as nurses and sanatorium attendants or susceptible groups such as Indians) the routine use of BCG would seem to be clearly indicated as pointed out in this *Journal* last year.¹

Where tuberculosis rates are still moderately high but control machinery somewhat more adequate, the x-raying of special groups of the population may be the primary method of choice. In this case, we still feel that the groups to be tested could most profitably be selected in the following order²: persons with suspicious pulmonary symptoms, contacts with known cases, general hospital admissions, members of specially susceptible racial groups, and workers in trades exposed to silica dust.

When the program of control has progressed further, the most promising procedure for obtaining a maximum result from the x-ray may well be the screening of the general population.

Finally, when the disease has been controlled as successfully as in Minnesota, Dr. Myers may be quite right in maintaining that every reactor to tuberculin should be viewed as a potential source of infection, and the program centered about that assumption.

The nice logic of this classification is somewhat marred by the fact that Danish authorities advocate the use of BCG not in the first of the five states outlined above, but in the fifth—on the ground that it is dangerous to create a non-immune

population and that the more we reduce naturally acquired immunity—the more important it is to create artificial herd-immunity by vaccination.

We can perhaps leave this problem to Minnesota and Denmark. Most American communities are still in the second, third, and fourth stages of the public health progress outlined above.

It is clearly desirable, however, that the individual health officer should size up his own local situation and decide on the most effective and economical use of the resources at his disposal. An engineer was once defined as “a man who can do for one dollar what any fool can do for two.” The health officer should be a good social engineer.

PRINCIPLES FOR CONSIDERATION IN JUDGING THE PROBABLE EFFECTIVENESS OF FEDERAL LEGISLATION DESIGNED TO IMPROVE THE HEALTH OF CHILDREN OF SCHOOL AGE*

Principles Relating to Scope and Content

1. The only criterion against which legislation can be measured is that it promotes continuing improvement in the health status of school age children. Many factors are involved. Specific legislation, however, is likely to be concerned with only certain phases. Three of these needing legislative attention at this time are: †

a. Health instruction and physical education

Here are included those organized programs within the school providing learning experiences in personal and community health, and instructional and practice periods of physical activity.

b. Health examination services

Here are grouped those activities of physicians, dentists, nurses, teachers, and other professional personnel through which the health status of school children

is appraised and diagnostic service begun.

c. Treatment services

Here are grouped the activities of physicians, dentists, nurses, and other health personnel; health department or other public agency; preventive, diagnostic, and treatment facilities; hospitals, clinics, and other community agencies which provide preventive, diagnostic, and treatment services to children.

2. These three phases are so closely interlocked that planning and provision for all of them are necessary in order to make maximum contribution to the health status of children. Legislation concerning any one or all of these should be evaluated in terms of principles contained in this statement.

3. These activities can be best carried out when the community provides:

- a. Adequate school facilities with sufficient trained professional personnel to meet the educational needs of all children in the community.

- b. A community health program which includes an organized local health unit adequately staffed with full-time personnel and physicians, dentists, nurses, and other health personnel available in the community.

- c. Facilities (hospital, health department, and other preventive, diagnostic and treatment facilities) for necessary preventive and diagnostic and treatment services

* This statement has been approved by the Council of the School Health Section and is published before transmittal to the Executive Board for adoption as an official statement of the Association in order to permit members and Fellows to review it and to offer criticisms and suggestions. Suggestions should be mailed promptly to the Executive Secretary, American Public Health Association, 1790 Broadway, New York 19, N. Y.

† It is recognized that rehabilitation and vocational training of the physically handicapped is an essential in providing for the total health needs of school children. Appropriate rehabilitation representatives should be consulted in making plans. Moreover, existing legislative and administrative provisions established on both federal and state levels under Public Law 113 to carry out these services should be utilized, and such amendments and additional appropriations as are necessary should be made to enable federal and state bureaus of vocational rehabilitation to provide services to all who come under their jurisdiction.

accessible to children from infancy through childhood.

Principles Relating to Health Instruction, Physical Education, and Health Examination Services

4. The general policies, organization, and plans for execution of the program should be planned jointly by the appropriate educational and health authorities at the federal, state, and local levels, after consulting with professional and other groups concerned.
5. Legislation should be sufficiently flexible to enable it to operate in accordance with a variation in state laws and administrative patterns.
6. Coördination at the federal level should be brought about through a joint committee representing the U. S. Office of Education, the U. S. Public Health Service, and the U. S. Children's Bureau, which shall give joint consideration to and advise the Federal Security Administrator on the establishment of policies and regulations, the basis for approval of state plans and recommendations regarding the allocation of funds. State superintendents of education and state health officers shall be consulted before the establishment of federal policies.
7. Legislation should contain provisions concerning purpose and scope of the program, general organization, and administrative structure. Details regarding operation and content of the program are matters for state planning in harmony with the general purpose of the legislation.
8. Education is the function of the schools. Safeguarding and promoting the health of the community is the function of health departments. The education departments should have full responsibility for the instructional progress, administrative responsibility for the conduct of all activities taking place in the schools, without regard to which agency operates the program of health examination services. Where health examination services are operated by education departments, the health department should be responsible for the professional consultation needed for establishing and maintaining standards, stimulating continued professional growth, and integrating the health service program in the school with the health program in the community.
9. All personnel rendering health services must be properly supervised by qualified members of their own profession.
10. The provision for consultant services on federal, state, and local levels should be planned jointly by educational, health, and rehabilitation authorities so as to avoid overlapping and duplication of services, and so as to gain participation and cooperation by all who serve children.
11. Funds should be allotted to the states on the basis of a single plan submitted jointly by state departments of education and of health after consulting with educational, medical, dental, nursing, and other professional groups concerned within the state.
12. Funds must be used for the initiation of new programs and services and the extension and improvement of existing programs. They must not be used to take the place of present expenditures from state and local sources.
13. Funds made available must be expended through public agencies under public control.
14. The same quality of health instructional programs, and health examination and diagnostic service for school children should be available

to children without regard to race, color, creed, nationality, or economic status.

15. Funds should be distributed so as to serve all children of school age in so far as the amount of funds allotted permit and with appropriate safeguards for the quality of service rendered.

*Principles Relating to Medical
Treatment Services*

16. Plans for the extension of medical treatment services for school age children should be developed by state health authorities in coöperation with medical, dental, nursing,

educational, and other professional and lay groups concerned in each state.

17. Federal funds are necessary to assist the states and local communities to provide medical treatment services for children of school age. Existing legislative and administrative provisions established on both federal and state levels to carry out appropriate sections of the Social Security Act should be utilized and such amendments and additional appropriations as necessary should be made to enable the Federal Security Agency and the states to assist in development of necessary medical treatment for children of school age.

Clearing House on Public Health Salary Information

STATUS OF SALARY STUDIES

THE gravity of the present situation as to public health salaries was recognized by the Executive Board of the American Public Health Association when it declared that the time had arrived for the Association to state what the services of public health workers are worth. In 1947, it recommended minimum salaries for physicians employed full time as administrators in public health programs. The recommended salaries range upward from \$6,000 for those without formal public health training but with two years of full-time successful experience. For those with a Master's degree in public health and two years' full-time successful experience the Executive Board recommended salaries ranging upward from \$8,500. Salaries exceeding \$12,000 were recommended for those who have heavy responsibilities and have achieved notable success.¹

Similarly the National Organization for Public Health Nursing recommended that no nurse employed full time in a public health position should receive less than \$2,400, and that those who have completed an approved program of study in public health should receive not less than \$2,520.²

These recommended salary ranges are above those paid by most public health organizations. Statements by the American Public Health Association and the National Organization for Public Health Nursing have been generally applauded and have in many areas been useful tools in raising salaries.

To study the salary problem further and to guide the Association in its

efforts to improve the picture in the United States, the Committee on Professional Education of the American Public Health Association appointed a Subcommittee on Salary Studies.*

This subcommittee has explored the subject in a preliminary manner. It is clear that the administrator, in his efforts to obtain funds and authorization for increased salaries, needs to know what salaries are paid in comparable organizations in the same geographic region. He also needs support from the A.P.H.A. by declarations of acceptable salary ranges for professional personnel other than health officers. His task would be easier if the plight of his staff and the essential rôle the health department plays in the community welfare were better understood by the public.

Several salary studies have been made or are now under way. The N.O.P.H.N. makes such studies annually for the field of public health nursing, and useful data are available for this field.³ The State and Provincial Laboratory Directors have recently completed a survey of salaries of laboratory workers on the state level. The Vital Statistics Section of the Association is currently studying salaries in its field. Those studies, completed or in progress, although excellent, are not adequate. There are few data

* The members of the Subcommittee are:
William R. Willard, M.D., *Chairman*
Richard F. Boyd, M.D.
Harold F. Dorn, Ph.D.
M. R. Kinde, M.D.
M. H. Merrill, M.D.
M. Allen Pond
Wilson T. Sowder, M.D.
Ernest L. Stebbins, M.D.
V. A. Van Volkenburgh, M.D.
Alberta B. Wilson, R.N.

available concerning salaries paid in city, county, and district health departments or in voluntary agencies. To secure such data and analyze them properly requires staff and funds not now available.

The studies which have been conducted, however, have defined certain problems that must be solved if salary studies are to achieve maximum validity and usefulness. As an example, positions of the same title in various health agencies often carry differing responsibilities which might reasonably be reflected in differing salaries. Conversely, many positions essentially the same in various agencies carry differing job descriptions, classification, and pay. Without taking these factors into account, it is impossible to make valid comparisons but to secure such information is laborious and time consuming. The most recent event is the request of the State and Territorial Health Officers Association to the U. S. Public Health Service to make a salary study. In meeting this request the Service has confined itself to a study of salaries in state health departments as of November, 1947. The results have been made available to the State and Territorial Health Officers Association and will be reviewed in the Clearing House next month. The tables show salaries of state health officers and program directors for Local Health Service, Maternal and Child Health, Public Health Dentistry, Public Health Laboratory, Public Health Nursing, Sanitary Engineering, Tuberculosis Control, and Venereal Disease Control. Another group of tables shows salaries by \$200 intervals, paid in state health departments to laboratory workers, nurses, physicians, sanitary engineers, and sanitarians below the top level. It is planned that this study shall be repeated annually and perhaps increased in scope.

The current study, therefore, is in effect a pilot study from which can be drawn the blue print for the more detailed information that is clearly needed; namely, salaries in various regions and types of health agencies and with more clear-cut job descriptions. Such analyses would not only contribute useful knowledge concerning salaries, but would be helpful as a step toward uniform job descriptions and classifications in various health agencies. It is the hope of the subcommittee that resources may be found to conduct such a study in cooperation with the U. S. Public Health Service, the State and Territorial Health Officers, the national voluntary agencies, and other appropriate organizations.

In the meantime the subcommittee is considering salary ranges for various types of public health positions. It hopes to make recommendations of salary ranges to the A.P.H.A. through the Committee on Professional Education. These ranges, if adopted, would establish minimum salary standards for additional positions. It is believed that this would provide a useful tool for many health administrators who are trying to raise salaries for their staffs. The subcommittee from time to time has published salary data from scattered health agencies in the Clearing House on Public Health Salary Information of the *American Journal of Public Health*. Any agency or person who has knowledge of a salary study of public health personnel or those in related fields is requested to cooperate with the Subcommittee on Salary Studies.

SOME PRINCIPLES REGARDING PUBLIC HEALTH SALARIES

THE following are excerpts from the report of a state health department to a state board studying salaries. This material is reproduced here because of its statement of general principles applicable to public health salary and recruitment problems being dealt with in other states.

"It is a recognized fact that the public health field is undergoing permanent expansion on the federal, state, and local levels of government. Accompanying this are the increased promotional activities of such private agencies as the National Tuberculosis Association, the American Social Hygiene Association, the National Foundation for Infantile Paralysis, and the American Cancer Society.

"Because this is a trend that has been in existence for some time and is a result of a nation-wide permanent program, its effect upon the salary situation cannot be brushed aside with the assertion that the medical recruitment problem is merely another symptom of a temporarily inflated wage market.

"In fact, a normally critical situation has been further aggravated by present economic conditions as indicated by the incomes of private physicians. Although no reliable statistics can be cited, the opinion is apparently unanimous among those having a knowledge of the field that there has been a phenomenal increase in physicians' incomes since 1939. Whatever progress has been made in convincing capable young doctors that the field of public health offers values to compensate for the lower monetary return from public service appears to be cancelled by the widened spread between incomes of private physicians and those of public health officials.

"Another independent factor having a profound effect upon the market has been the expansion of the veterans' hospital program. This cannot be classed as short-term competition.

"The current large number of vacancies is not merely a reflection of departmental expansion or accumulation of war-duration vacancies. Rather, they are the inevitable result of the factors referred to above.

"A timely factor to consider is the recent federal recruitment program for all types of public health positions. It is presumed that the salary board has carefully looked into this development. However, according to information received in March, 1947, from the U. S. Public Health Service, in the Children's Bureau, which follows a civil service pattern for its title structure, the salary of the position designated as 'entrance grade' ranged from \$5,905 to \$6,862; that of the 'regular grade' ranged from \$7,102 to \$8,059.

"It is admitted that the weight which the board studying salaries gives to federal salaries is a matter of broad policy. However, even if the policy of generally ignoring federal rates is adopted, it can be reasoned that it could be relaxed for a class of positions under exceptional circumstances. The continuance and in some respects the permanent peacetime expansion of public health programs of federal agencies along with the employment demands of the Veterans' Administration are cases in point.

"The training required of a public health physician is the same as that required of the physician who treats the ill and injured up to the point of entering training for the specialty of public health. During the one and one-half years of postgraduate academic and field training of the public health physician, he learns to analyze the health problems and improve the health of the community rather than to diagnose and treat the illness of the individual. To be a successful health officer the physician must be able to utilize statistics to determine the health needs of his commu-

nity; he must be skilled in the diagnosis of communicable diseases and their methods of transmission and control; he must have administrative ability; he must have a keen sense of business methods in order to prepare his budgets and wisely utilize the tax dollars allotted to him; he must be skilled in methods of educating the public relative to public health measures, and he must have diplomacy and tact to deal successfully with other government officials and the public.

"The physician specializing in a clinical branch of medicine requires

training over a comparable period of time in his clinical specialty. Recognition has been given to the value of this additional clinical training by an upward reallocation during the past three years of the salaries of a great many physicians in the state hospitals who are thus qualified. Equal recognition should be given to the training required of a public health physician who, in addition to a certain amount of specialized clinical training, must possess other training not required of physicians whose duties are to treat individual patients."

1947 Directory of State Health Officers

The 1947 Directory of State and Territorial Health Authorities recently became available. It shows not only

health officers but directors of divisions and bureaus. U. S. Government Printing Office, Washington 25, D. C. 15 cents.

PUBLIC HEALTH IN SWEDEN

"A good test of the social standard achieved by a nation is the interest shown in public health." This sentence opens a brief article in the *American-Scandinavian Review* for December, 1947, reprints of which are available from the American-Swedish News Exchange, 630 Fifth Avenue, New York 20. The author is Dr. Arvid Myrgård who is a district physician in the south of Sweden.

Sweden has had a government sponsored health insurance fund for some years. In 1946, a new law was passed which will make it obligatory for the whole nation by 1950. Health control and medical control are combined in one administration which, this report says, is a happy solution in a country as thinly populated as Sweden, and points out that this double function has a long historic tradition, district physicians having been instructed as early as 1720 to pay attention to the living habits of the people and to correct unsanitary conditions as well as administer to the sick.

Sweden's public health system is administered through 24 districts for a population of something over 6½ million. This would average about 260,000 persons per district which is the approximate population planned for New York City's 31 health center districts. This little pamphlet should be of interest to American public health workers.

PLANNING YOUR CHILDREN

Recently triplets were born to a board member of the Planned Parenthood Federation of America. He announced that although he and his wife did not plan for triplets, they did plan their children.

Apropos of planning your children, the Public Affairs Committee has just published its pamphlet No. 136 on *Planning Your Family*. It contains the experience of a number of public health workers on the relation of planned parenthood to public health.

Felix J. Underwood, M.D., Health Commissioner of Mississippi, says that in the South, planned parenthood programs are a necessary and integral part of the tuberculosis control program.

Available from the Public Affairs Committee, 22 East 38 Street, New York 16, at 20 cents each.

COLORADO HAS A HEALTH BULLETIN

The revolution in the Colorado State Health Department is further symbolized by *Colorado Health News*, Volume 1, Number 1, which appeared in January, 1948. This first issue pictures the newly-reorganized state health department in which there are four main divisions—one for preventive medicine services, one for local health services, one for sanitation, and one for general health services. The vitality of the reorganized department is indicated also by the fact that 34 additions have been made to the staff since July 1, 1947. Among these are the Director of the Laboratories Section, George W. Stiles, M.D.; Director of Maternal and Child Health, Marion Dressler, M.D.; Director of Venereal Disease Control, James R. McDowell, M.D.; Director of Veterinary Services, Martin Baum, D.V.M.; Director of Health Education, Norma Johannis; and Director of Hospital Facilities, Herbert D. Moe.

Another interesting announcement in this first issue is of an agreement between the City and County of Denver and the State Health Department to

combine their Vital Statistics Services in one unit to be located in the State Health Department and under the direction of Fred W. Beesley, D.D.S.

EACH HELPS IN HIS OWN WAY

Money is not the only coin through which community agencies can express their support of community projects. An excellent illustration of this fact is in a money raising brochure, *Children Calling*, put out by the Children's Hospital of Michigan in Detroit. This brochure was the contribution of a local advertising agency, MacManus, John & Adams, Inc., to the future of the hospital. Its photographs and its make-up would do the advertising concern proud even if it had been prepared for its most expensive customer. In appealing pictures, the story is told of the Children's Hospital services from the time the child enters the hospital until he is discharged from the convalescent home or the clinic. This is a striking illustration of bringing varied community resources to bear on one's problem.

SAFETY FOR THE HOUSEHOLD

If you have broadened your horizons to the extent of including some activity in the elimination of household accidents, here's a publication that should be of interest to you. *Safety for the Household* is a 200 page pamphlet published by the National Bureau of Standards. Although written mainly for the average present-day household, the booklet provides information that is also of value in the construction and safe operation of schools, hotels, stores, industrial plants, etc. Chapters on gas, building construction, refrigerants, fire prevention, plumbing, and electrical equipment are only some of the special items that have been prepared, all of them by qualified specialists from the Bureau. In preparing the booklet, recognition has been taken of possible new sources of accidents in the home brought

about by recent trends in home design, household equipment and modern toys. This publication, also known as *NBS Circular 463* can be obtained from the Superintendent of Documents, Washington 25, D. C., for 75 cents.

WHERE OHIO NOW STANDS

When *Local Health Units for the Nation*, the report of the Association's Subcommittee on Local Health Units, was being prepared in 1944, the best that could be agreed upon as a districting plan for Ohio was 53 units to cover the 88 counties, 10 of the 53 with populations of less than 50,000.

As late as July, 1947, three-fourths of the state's population in 61 counties were served through 70 local health departments in charge of full-time health officers. These 70 departments covered 111 of the 203 jurisdictions set up by the Ohio public health law, leaving 92 with a fourth of the state's population in charge of part-time health officers.

The present State Health Officer, John D. Porterfield, M.D., now suggests a much bolder plan than was proposed in *Local Health Units for the Nation*. For the consideration of Ohio citizens, he suggests that adequate service could be given to every person in the state through 37 local health departments, no one of them serving less than a county and all its contained cities, and all but 8 of them serving 2 or more counties. In this plan the smallest population made up of 3 counties is nearly 70,000.

In developing his plan, Dr. Porterfield has secured the support of many citizen groups in the state. Although it is to be expected that there will be delays and changes in putting it into effect, it is nevertheless a realistic approach to the problems of financing and staffing local public health service in the face of present-day personnel shortages.

Coincident with the development of this plan, the State Health Department

has been reorganized. The department has also published a pamphlet outlining the legal procedures involved in combining health districts or in contracts for public health service to a district from a neighboring one. These are the two methods provided by the Ohio law for consolidating existing health jurisdictions.

ANNUAL REPORTS

The 29th Annual Report of the Commonwealth Fund for 1947 representing the end of Barry Smith's 26 years of Directorship of the Fund, takes a backward look to see what the Fund has done and tried to do thus far. This backward look is a contribution to the social history of the last quarter of a century that is well worth attention by the public health worker.

A Decade of Doing is the title of a brief report of the first 10 years' activities of the National Foundation for Infantile Paralysis. In a little pamphlet of 20 pages about the size of a check-book, it manages to tell the background of the Foundation, what special events have taken place, what research has accomplished and what is ahead—particularly in better staffing of polio centers, in creating convalescent care and in improving opportunities for handicapped men and women.

Public Health in a Changing World is a report for the 2 years, 1945 and 1946, of the Birmingham-Jefferson County (Ala.) Health Department. Because it is dedicated to the late Judson D. Dowling, M.D., who was its first health officer in 1917 and served in that capacity for nearly all of the 30 years of the department's existence, it is also a summary of public health in the years 1917-1947. As such, it contains a very brief historical bird's-eye of the scientific, social and economic facts that affected public health—the two World Wars and the great depression between, Hiroshima, immunology, the Rh Factor,

psychosomatic medicine, and many others. The Jefferson County health picture is portrayed in the perspective of these events in an attractively packaged booklet.

Through the War Years, 1941-1947 is the six year report of the Des Moines County Health Unit which has the distinction of being the only local full-time health department in the state. It is a good workmanlike report which tells the story of the health department activities during the war years in a community that had a war ordnance plant and whose population increased about 50 per cent during the period.

COMMUNITY JUVENILE DELINQUENCY PROGRAMS

The conference technique of dealing with community problems is in no present danger of falling into disuse. Control of juvenile delinquency is currently being approached in this among other ways. In November, 1946, the Attorney General of the United States called a national conference on prevention and control of juvenile delinquency to study and make recommendations for action in each community.

In January, President Truman issued a proclamation calling for similar state and local conferences throughout the nation in April, 1948. Among the tools available for these conferences are 18 pamphlets representing the results of the various panel discussions of the 1946 conference. Included are a wide range of subjects relating to juvenile delinquency. These may be purchased from the Government Printing Office, Washington, D. C., for from 10 to 25 cents each or \$2.65 for the set. There are also special rates for quantity orders.

Available also is a *Handbook of First Steps in Organizing State or Local Conferences on Prevention and Control of Juvenile Delinquency*. This detailed guide has the why and how of such local conferences. If your community

combine their Vital Statistics Services in one unit to be located in the State Health Department and under the direction of Fred W. Beesley, D.D.S.

EACH HELPS IN HIS OWN WAY

Money is not the only coin through which community agencies can express their support of community projects. An excellent illustration of this fact is in a money raising brochure, *Children Calling*, put out by the Children's Hospital of Michigan in Detroit. This brochure was the contribution of a local advertising agency, MacManus, John & Adams, Inc., to the future of the hospital. Its photographs and its make-up would do the advertising concern proud even if it had been prepared for its most expensive customer. In appealing pictures, the story is told of the Children's Hospital services from the time the child enters the hospital until he is discharged from the convalescent home or the clinic. This is a striking illustration of bringing varied community resources to bear on one's problem.

SAFETY FOR THE HOUSEHOLD

If you have broadened your horizons to the extent of including some activity in the elimination of household accidents, here's a publication that should be of interest to you. *Safety for the Household* is a 200 page pamphlet published by the National Bureau of Standards. Although written mainly for the average present-day household, the booklet provides information that is also of value in the construction and safe operation of schools, hotels, stores, industrial plants, etc. Chapters on gas, building construction, refrigerants, fire prevention, plumbing, and electrical equipment are only some of the special items that have been prepared, all of them by qualified specialists from the Bureau. In preparing the booklet, recognition has been taken of possible new sources of accidents in the home brought

about by recent trends in home design, household equipment and modern toys. This publication, also known as *NBS Circular 463* can be obtained from the Superintendent of Documents, Washington 25, D. C., for 75 cents.

WHERE OHIO NOW STANDS

When *Local Health Units for the Nation*, the report of the Association's Subcommittee on Local Health Units, was being prepared in 1944, the best that could be agreed upon as a districting plan for Ohio was 53 units to cover the 88 counties, 10 of the 53 with populations of less than 50,000.

As late as July, 1947, three-fourths of the state's population in 61 counties were served through 70 local health departments in charge of full-time health officers. These 70 departments covered 111 of the 203 jurisdictions set up by the Ohio public health law, leaving 92 with a fourth of the state's population in charge of part-time health officers.

The present State Health Officer, John D. Porterfield, M.D., now suggests a much bolder plan than was proposed in *Local Health Units for the Nation*. For the consideration of Ohio citizens, he suggests that adequate service could be given to every person in the state through 37 local health departments, no one of them serving less than a county and all its contained cities, and all but 8 of them serving 2 or more counties. In this plan the smallest population made up of 3 counties is nearly 70,000.

In developing his plan, Dr. Porterfield has secured the support of many citizen groups in the state. Although it is to be expected that there will be delays and changes in putting it into effect, it is nevertheless a realistic approach to the problems of financing and staffing local public health service in the face of present-day personnel shortages.

Coincident with the development of this plan, the State Health Department

has been reorganized. The department has also published a pamphlet outlining the legal procedures involved in combining health districts or in contracts for public health service to a district from a neighboring one. These are the two methods provided by the Ohio law for consolidating existing health jurisdictions.

ANNUAL REPORTS

The 29th Annual Report of the Commonwealth Fund for 1947 representing the end of Barry Smith's 26 years of Directorship of the Fund, takes a backward look to see what the Fund has done and tried to do thus far. This backward look is a contribution to the social history of the last quarter of a century that is well worth attention by the public health worker.

A Decade of Doing is the title of a brief report of the first 10 years' activities of the National Foundation for Infantile Paralysis. In a little pamphlet of 20 pages about the size of a check-book, it manages to tell the background of the Foundation, what special events have taken place, what research has accomplished and what is ahead—particularly in better staffing of polio centers, in creating convalescent care and in improving opportunities for handicapped men and women.

Public Health in a Changing World is a report for the 2 years, 1945 and 1946, of the Birmingham-Jefferson County (Ala.) Health Department. Because it is dedicated to the late Judson D. Dowling, M.D., who was its first health officer in 1917 and served in that capacity for nearly all of the 30 years of the department's existence, it is also a summary of public health in the years 1917–1947. As such, it contains a very brief historical bird's-eye of the scientific, social and economic facts that affected public health—the two World Wars and the great depression between, Hiroshima, immunology, the Rh Factor,

psychosomatic medicine, and many others. The Jefferson County health picture is portrayed in the perspective of these events in an attractively packaged booklet.

Through the War Years, 1941–1947 is the six year report of the Des Moines County Health Unit which has the distinction of being the only local full-time health department in the state. It is a good workmanlike report which tells the story of the health department activities during the war years in a community that had a war ordnance plant and whose population increased about 50 per cent during the period.

COMMUNITY JUVENILE DELINQUENCY PROGRAMS

The conference technique of dealing with community problems is in no present danger of falling into disuse. Control of juvenile delinquency is currently being approached in this among other ways. In November, 1946, the Attorney General of the United States called a national conference on prevention and control of juvenile delinquency to study and make recommendations for action in each community.

In January, President Truman issued a proclamation calling for similar state and local conferences throughout the nation in April, 1948. Among the tools available for these conferences are 18 pamphlets representing the results of the various panel discussions of the 1946 conference. Included are a wide range of subjects relating to juvenile delinquency. These may be purchased from the Government Printing Office, Washington, D. C., for from 10 to 25 cents each or \$2.65 for the set. There are also special rates for quantity orders.

Available also is a *Handbook of First Steps in Organizing State or Local Conferences on Prevention and Control of Juvenile Delinquency*. This detailed guide has the why and how of such local conferences. If your community

conference has not been held you will want this manual from the Continuing Committee, The National Conference on Prevention and Control of Delinquency, Washington, D. C.

HOW LOCAL HEALTH COUNCILS ARE BUILT

The National Health Council has recently published *Stepping Stones to a Health Council* by Yolande Lyon. It answers the questions the intelligent layman might have about a health council, what it is, and what it will do for a community, who belongs to it, who starts one, and how. It is written in a simple easy style with frequent headings to guide the reader. It should be in the hands of every lay and professional person interested in finding ways of improving his community health program.

Stepping Stones is geared to the situations existing in urban areas where techniques of coöperation between diverse voluntary and official health agencies need to be developed more definitely than to rural or sparsely settled areas where there has been little development of health services. It is the plan of the Council to prepare a further manual designed especially for rural areas.

Stepping Stones is available from the National Health Council, 1790 Broadway, New York 19, at 25 cents per copy; 20 cents for orders of 25 or more.

THE COST OF COMMUNITY FAILURES

The Public Health Federation of Cincinnati has recently published *We Pay With Our Lives—A Story of Life and Death in Cincinnati* in terms of what community apathy, ignorance, and poverty cost in lives. This study of the mortality figures for the city, made by

the Federation's Director of Research, Floyd P. Allen, M.D., leaves no doubt as to the high correlation between death rates and such social and economic factors as family income, housing, schooling, etc. One-fourth of Cincinnati's population lives in the Basin, an old slum area on the Ohio River where buildings are old, overcrowded, without play spaces, and occupied by the lowest income groups, three-quarters of them Negroes. In the Basin the death rates for tuberculosis, pneumonia, accidents, homicide, and infant mortality are in all instances twice as high for whites as outside the Basin, and for Negroes in the Basin uniformly higher than for whites in the same area. *We Pay with Our Lives* is no poetic but a deadly realistic title for this example of a community looking at the facts.

THE OHIO SANITARIAN PUBLISHES AGAIN

Volume 3, No. 1 of the *Ohio Sanitarian* marks the revival of this publication, now the organ of the Ohio Association of Public Health Sanitarians, a quarterly designed primarily for the sanitarian in city and district offices of Ohio. The current issue includes a section on technical hints, another on recent legislation proposed or enacted in the State of Ohio, a list of the personnel active in the field of environmental sanitation in various state district offices plus "Personals." The Ohio Association of Public Health Sanitarians is an outgrowth of the former Ohio Conference of Milk and Food Sanitarians organized in the late 30's. E. A. Graber, Milk and Food Sanitarian of the Ohio State Department of Health, Columbus 15, is Secretary-Treasurer of the Association.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Sexual Behavior in the Human Male—By A. C. Kinsey, W. B. Pomeroy, and C. E. Martin. Philadelphia and London: Saunders, 1948. xxv and 787 pp. Price, \$6.50.

In view of the central importance of reproduction in the life cycle of any living organism, it is extraordinary that basic scientific data with regard to the sex activities of the genus *Homo* have been almost wholly lacking. Our views on this essential factor in the life history of the human species have been dominated by social traditions and moral aspirations. Even single case histories have been of a highly fragmentary nature; and studies including sufficient quantitative data to have statistical significance simply nonexistent.

The authors of the present volume have approached the subject with the approved techniques of the biologist. (The senior participant has published a report on a single species of gall wasp based on 150,000 individual specimens.) The investigation of Professor Kinsey and his associates is planned ultimately to include 100,000 human case histories. It is sponsored by the Committee on Research in Problems of Sex of the National Research Council and has the generous support of the Rockefeller Foundation as well as that of the University of Indiana where its authors are faculty members in the Department of Zoology. It is a 20 year "fact-finding survey in which an attempt is being made to discover what people do sexually and what factors account for differences in sexual behavior among individuals and among various segments of our population." At present some 12,000 individual case histories have

been collected, and this first volume of the studies is an analysis of approximately 5,300 white males included in the group.

The project is a bold one. Professor Kinsey reports that "there were attempts by the medical association in one city to bring suit on the ground that we were practising medicine without a license, police interference in two or three cities, investigation by a sheriff in one rural area, and attempts to persuade the University's administration to stop the study or to prevent the publication of the results, or to dismiss the senior author from his university connection, or to establish a censorship over all publications emanating from the study." Even greater courage, perhaps, was needed to face the inherent difficulties in the task itself; but these difficulties have been met and overcome with persistence and with high technical skill. While the present sample of 5,300 is insufficient for many refined correlations, which future extensions will make possible, it includes a nationwide geographical coverage (fully representative of the northeastern quarter of the United States) and most extensive social coverage (inmates of penal institutions, the underworld in general, laborers, clerks, farmers, business executives, lawyers, physicians, college professors, and clergymen).

The data were not obtained by questionnaires (which are of very doubtful value in such an area) but by intimate personal interviews, carried out by Kinsey (who himself conducted 58 per cent of the interviews) and five other trained experts. In informal sympathetic and objective conversation,

answers have been obtained with regard to 521 possible items of personal experience, the results being recorded in a code known only to the investigators and never reduced to writing to insure their absolutely confidential nature. Data have been analyzed by the stratified sampling method and results checked and verified by the soundest statistical procedures.

For interpretation on a national scale, the data for the observed sample populations are translated (for various age groups and social groups) into national terms by correction for the proportions of such groups given by United States Census figures.

The first basic fact revealed by this preliminary study is the actual incidence of activity of the sex glands as evidenced by accomplishment of an orgasm. The total incidence of such sexual climaxes from adolescence to the age of 85 averages 2.34 per week for the United States male population. From adolescence to the age of 30 years, the figure is 3.27.

Orgasm is accomplished by six different methods: masturbation, nocturnal emissions, heterosexual petting, heterosexual intercourse, homosexual relations, and intercourse with animals; and three-quarters of the male population have experienced two or more of such outlets. Individual patterns vary to a most astonishing degree. Single instances are reported in which either masturbation, or nocturnal emissions or intercourse or homosexual relations accounted for the total outlet. Two per cent of the population have experienced 5 or 6 of the possibilities. By the age of 20 years, 92 per cent of all males report orgasm through masturbation; 77 per cent through nocturnal emissions; 73 per cent through premarital intercourse; 37 per cent through homosexuality; and 24 per cent through petting procedures. A second major conclusion from the study is, then, that practices which society has

labelled as "abnormal" and "degenerate" and psychotic are major phases of normal human behavior—whether we like it or not.

Incidentally, it should be noted that homosexual experience does not mean that the individual is "*a homosexual*." There is the usual biological gradient between pure homosexuality and pure heterosexuality.

A third major revelation of this study is the wide difference in type of sexual outlet in different social classes. The data are analyzed in detail by various occupational groups; but the main facts are most clearly presented by the educational level attained by the individual, which the author rightly interprets as a measure of social status. Three major groups are analyzed, including boys who have only a grade school education, those who go through high school, and those who reach the college level. Total sexual outlet is greatest in the second of these groups (9th–12th grade) and lowest in the college group. The total sexual activity for the high school group is 10–20 per cent above that for the grade school group, and 20–30 per cent higher than for the college group. (It should be noted that these variations have nothing to do with educational experience *per se*. They are manifest both before and after actual school experience.) The major differences appear in the type of outlet. At the age of 20, the grade school group shows 66 per cent and the college group 94 per cent with experience of nocturnal emissions; the grade school group, 14 per cent with experience of orgasm due to petting and the college group 46 per cent; while premarital intercourse is experienced by 85 per cent of the grade school group against only 44 per cent of the college group. Masturbation experience is over 90 per cent in all groups; and homosexual experience highest in the high school group (43 per cent)—a puzzling phenomenon.

In general, the differences noted above are clearly mirrored in the emotional reactions of the individuals interviewed. The mores of the grade school group regard masturbation (in spite of its common prevalence in youth) and petting activities with an abhorrence not found in the college group; while feeling in regard to extramarital heterosexual relations is exactly reversed.

Incidentally, it should be noted that there is little evidence in this study of deterioration in sexual habits or of any harmful effects of military service. Correlative evidence as to past experience indicates that younger and older generations of the college level show a greater incidence of petting experience in recent years; while at grade school level the younger generation becomes active at a somewhat earlier age in premarital intercourse and shows an increase in masturbation and petting experience. Otherwise, the records (at similar ages) for men over and under 33 years of age are identical. The fundamental patterns of sexual experience are set by the middle teens and they are set by the mores of the social group to which the individual belongs.

Perhaps the most important conclusion from this whole study is that our conception of what is "normal" sexual behavior must be radically revised. What is "desirable" is another question; and "desirable" ends may be made more nearly "normal" by changing our mores. We must recognize facts, however, now that we have them. Our present legal standards are based on a point of view not dissimilar to the assumption that all men are normally six feet tall and that those below this height must be abnormal and degenerate.

The facts brought out in Professor Kinsey's book should be given serious consideration by all persons who are engaged in personal counselling services, such as physicians, mental hygien-

ists, social workers, prison executives, and military authorities. Alan Gregg says in his brief preface to the volume, "These studies are sincere, objective, and determined explorations of a field manifestly important to education, medicine, government, and the integrity of human conduct generally. They have demanded from Dr. Kinsey and his colleagues very unusual tenacity of purpose, tolerance, analytical competence, social skills, and real courage. I hope that the reader will match the author with an equal and appropriate measure of cool attention, courageous judgment and scientific equanimity."

C.-E. A. WINSLOW

140 Million Patients—By Carl Malmberg. New York: Reynal and Hitchcock, 1947. 242 pp. Price, Paper, \$.95, Cloth, \$2.75.

In his capacity as public relations advisor and information specialist for the U. S. Public Health Service and, recently, as chief investigator for the Sub-Committee on Health and Education of the Senate Committee on Labor under the chairmanship of Senator Murray, the author has been able to assemble a mass of factual data which demonstrate clearly that there is much room for improvement in the health of the nation. The monograph is readable, interesting, and for the most part thoroughly convincing. It marshals authentic information bearing upon the dual problems of medical care in the United States and of national compulsory medical insurance in a more effective manner than any volume previously published on this subject. It will become the bible of proponents of compulsory medical insurance.

Praise for the interesting manner in which this valuable information has been presented must be tempered by regret that the journalistic experiences of the author have persuaded him to overdramatize some of the factual material,

which may mislead many lay readers who are not in possession of all the medical facts. Medical authorities who condemn their professional colleagues for wrong diagnostic and therapeutic practices are quoted frequently. When reread in relation to the rest of the texts from which these quotations are derived, they prove for the most part to be admonitions employed for the purpose of driving home the author's lessons to his colleagues.

In the chapter entitled "How Good Is American Medical Care?" Mr. Malmberg includes a number of gruesome mistakes made by hospitals and individual physicians. His examples are quoted both from newspapers and from authoritative medical journals. When read in unrelieved sequence they will surely instill a fear in the uncritical reader that he is living in a medical wilderness. By the time he has reached page 152, the average reader will have developed a profound anxiety state, convinced by the evidence that there is little hope for him at the hands of an average practitioner or specialist. He is then in proper shape to accept the "Prescription for Better Health" which is next offered to him, national compulsory medical insurance. The reader is not made aware that many of the hospitals in which the author describes conspicuous examples of neglect and malpractice are wholly supported and operated by government. For example, the tragic story of Alice at the close of the chapter on "How Good Is American Medical Care?" ended in Gallinger Hospital which is operated by the government of the District of Columbia presumably under the supervision of a special committee of the House of Representatives.

No one can take issue with the main theses of this monograph, that medical care is grossly inadequate in many parts of the country, that the health of people of low incomes, even those who live in

the most privileged urban centers, is often jeopardized by "too little and too late," and that morbidity and mortality rates for many preventable diseases are inexcusably high for one of the most civilized countries of the world. The question troubling all men of good will is how best shall we proceed to correct these deficiencies. In writing his prescription of a remedy, Mr. Malmberg endorses the Wagner-Murray-Dingell Bill which would levy a special and general tax upon all citizens in the nation and in return promise all workers complete and adequate medical care wherever they may live.

Before the government can carry out such an obligation with a reasonable measure of success, it must educate many more physicians, dentists, nurses, medical auxiliaries, and public health workers; arrange for their more equitable distribution throughout the underprivileged sections of the country; help local communities to build and staff more hospitals, health centers, and public health laboratories; provide full-time local health departments wherever they are lacking; persuade medical schools to awaken to their social obligations and accept a share of responsibility for the quality of medical services provided by physicians and hospitals in their area; and, last but not least, educate the public and the medical profession concerning medicine in the changing order. This reviewer offers no brief in defense of that large segment of the medical profession which has resisted progress.

The question, then, is whether we should close our eyes to the pitfalls which lie ahead and take one grand leap, or whether we should proceed to correct the deficiencies in our medical care system by purposeful steps such as those outlined in the previous paragraph. Mr. Malmberg, who favors the first alternative apparently has not considered the advantages of the second, for he does not mention the four year

study of medical care made by the Committee on Medicine and the Changing Order of the New York Academy of Medicine. He makes no reference to the ten monographs on various parts of the problem published by the Academy during the last two years, nor to the final summary report entitled "Medicine in the Changing Order" which appeared in March, 1947,* and contains its recommendations. In this report, as well as in statements made by the President of the Academy at Senate Hearings on medical care during 1946 and 1947, a proposed rôle of government is outlined and grants-in-aid to the states and local communities are advocated for the support of state programs of prepaid medical care, changes in medical education, encouragement of medical group practice, promotion of medical research, establishment of adequate local health services, and health education of the public.

The Academy favors voluntary medical insurance at this time because it provides operational flexibility and broad possibilities for experimentation with methods of providing comprehensive medical care such as group medical practice, and of paying for such medical services by capitation or capitation plus salary in a manner which may insure high standards of preventive as well as curative medicine. The Health Insurance Plan of Greater New York (HIP) is an example of the type of experimentation which the Academy has in mind. On the other hand, it also sees advantage in the adoption of compulsory medical insurance by one or more states so that there may be comparable experiences with voluntary and compulsory systems.

After four years of intensive study, the Academy finds itself opposed to national compulsory medical insurance at this time chiefly, although not entirely,

because the medical profession and medical institutions of this country are unprepared for a radical nation-wide program. The Academy is convinced that such a revolutionary change in medical care at this time would be followed inevitably by serious deterioration of medical standards as in New Zealand and be detrimental to the health of the nation. While admitting most of Mr. Malmberg's premises, it believes that the goal which he has in mind can be reached more rapidly by methods which are decidedly less hazardous.

Mr. Malmberg's book, *140 Million Patients*, should be required reading for every health worker and every physician in the country. Then, before accepting his prescription for better health, they should also read *Medicine in the Changing Order*, published by the Commonwealth Fund. GEORGE BAEHR

Practical Psychiatry and Mental Hygiene—By Samuel W. Hartwell, M.D. New York: McGraw-Hill, 1947. 439 pp. Price, \$3.75.

This is a new textbook on psychiatry and mental hygiene written particularly for nurses. It was written with the purpose of helping the student develop a dynamic interest in psychiatry, of making psychiatry more easily understood, and of making the teaching of psychiatry practical. The author has succeeded well in these objectives. The text is simply and clearly written. There is a minimum of technical jargon and an excellent glossary is provided as reference for the necessary technical terms which are introduced.

The author prepares the nurse for understanding the symptomatology of the various clinical syndromes by giving a brief theoretical background drawn from the various psychological schools of thought. In general the orientation is that of the psychoanalytic clinical approach. There is a general discussion of

* Reviewed in this *Journal*, 37, 9:1188 (Sept.), 1947.

the etiology of mental disease and a description of the various mental symptoms which the nurse may encounter. Practical suggestions are given regarding the taking of a psychiatric history and an outline for such a history is provided as an appendix.

The various syndromes are presented as in the standard classification of the American Psychiatric Association. In discussing the treatment of the various mental disorders the aim is to give to the nurse practical suggestions which will be of help to her, rather than discussion of the intricacies of the psychiatric treatment. The section on mental hygiene is especially well done. The discussion of the psychological development of the child and the parent's rôle in this development should be very helpful not only to the nurse as a professional person but to a mother as well. While the text is written for nurses and the practical suggestions for treatment are particularly appropriate for the nurse, the general simplicity and clearness make it a valuable text for a group who do not have a preliminary medical education. JAMES M. CUNNINGHAM

Cornell Conferences on Therapy, Volume II—*Edited by Harry Gold, M.D., Managing Editor, and Editorial Board. New York: MacMillan, 1947. 354 pp. Price, \$3.75.*

This second volume records 16 selected clinical conferences of the Department of Medicine and the Department of Pharmacology at Cornell University Medical School—New York Hospital, with participation of a wide range of additional practitioners. The conferences, designed "to promote the practice of therapeutics based on sound pharmacological principles," deal with a variety of subjects, all problems in therapy. Of particular interest to the health officer are the discussions of poliomyelitis, meningitis, syphilis, rheumatic fever, and malaria.

In a time when practices and standards of therapy are changing from day to day, this publication is not intended as the last word in therapy, but as a report of progress starting from recognized fundamentals. The attitudes of a group of distinguished participants, based on facts and opinions, are presented in dialogue form, with introductory remarks and a concise summary for each presentation.

In addition to providing a general review of a number of therapeutic problems selected on the basis of their frequency and common interest, the editors have illustrated a commendable teaching device. The integration of fundamental principles with their realistic application is worthy of copying in a number of fields. It is regrettable that the practice is not more widespread in teaching preventive and therapeutic medicine.

ROBERT DYAR

Meals for Millions—Final Report of the New York State Joint Legislative Committee on Nutrition—*Chairman, Senator Thomas C. Desmond. Newburgh, N. Y.: State Joint Legislative Committee on Nutrition, 1947. 213 pp. Free.*

The New York State Joint Legislative Committee on Nutrition has sought to explore this subject from many angles and this report which is *Legislative Document* (1947) No. 61, includes testimony presented before the Committee by about 30 persons, including among others Anton J. Carlson, Ole Salthe, Callie Mae Coons, Robert S. Goodhart, James R. Wilson, Harold R. Sandstead, Edward R. Schlesinger, Norman Jolliffe, and Otto A. Bessey.

The volume represents a good attempt to bring down to practical levels the discoveries in many laboratories, and the analysis of the problem as it affects New York State has implications elsewhere.

REGINALD M. ATWATER

Diseases Transmitted from Animals to Man—By *Thomas G. Hull, Ph.D. (3rd. ed.) Springfield, Ill: Thomas, 1947. 571 pp. Price, \$10.50.*

This third edition is more comprehensive than the earlier editions. The new chapters on rickettsial and virus diseases have broadened its scope. Public health workers will find it most interesting and practitioners of human and veterinary medicine will find a common ground.

Under each disease there is a brief discussion of its history, epidemiology, bacteriology, pathology, symptomatology, and control. Some chapters deal with all these phases in an excellent manner. The chapters on Tuberculosis, Swine Erysipelas, Listerellosis, Ornithosis, Plague, Typhus Fever, Rocky Mountain Spotted Fever, and Jungle Yellow Fever are outstanding. Other chapters have been weakened by repetition of investigational reports of 15 to 20 years ago, or have presented only one aspect of the problem which does not give the reader the broad discussion he seeks.

There are many statements throughout the book that cannot go unchallenged or that have been given too much emphasis. The discussion of tuberculosis points out that avian tuberculosis is capable of causing widespread disease in swine and sheep. It is hardly possible that the author believes that avian tuberculosis can be as serious to sheep as it has been to swine. In the summary for brucellosis it is emphasized that *Brucella abortus* attacks man at rather rare intervals. That may be true if based on the 1928 study of McAlpine and Mickle, but if we turn to 1946 and note that there are six times as many cases reported in a population that has a much higher percentage of pasteurized milk, the low pathogenicity theory of *B. abortus* for man is not supported. In the discussion of the rôle of animals and birds in the transmission of disease

it is not thought that the author meant to stress the importance of the chicken as a reservoir of brucellosis or swine erysipelas. Neither of these diseases has been possibly traced to infected fowls except on rare occasions.

The reviewer does not believe salmonella should be considered only as a food infection, but should be more broadly thought of as the cause of an infectious disease that may be due to occupational hazards, or spread directly from man to man, or animal to man, or man to animal.

The statement "that post-vaccinal paralysis is due to rabies fixed-virus contained in the vaccine is receiving more support today," is probably too enthusiastic. It is the belief of most workers in this field that post-vaccinal paralysis is an immunity phenomenon. The meticulous attention given to the preparation of anti-rabies vaccine, under the supervision of the Bureau of Animal Industry and the Public Health Service in which every possible test is performed before vaccines are released, would seem to prevent any virulent virus material being included in the vaccine. In regard to post-vaccinal rabies, today most veterinarians and investigators believe that such cases are due to active infection existing in the animal before it is immunized.

Under the discussion of Pox Diseases of Man and Animals the author states that between 30,000 and 60,000 cases of smallpox occur annually. It has been fifteen years or more since 30,000 cases were reported annually. In 1946 there were 356 cases reported to the U. S. Public Health Service and in 1945 only 345.

The author in his discussion of histoplasmosis states that the disease caused by *Histoplasma capsulatum* is invariably fatal. Investigations since 1940 suggest that this is a widespread disease in the central United States which has a low mortality rate.

It is a debatable question whether any serologic tests for leptospirosis are satisfactory. There has been much discrepancy of results in various investigators' and practitioners' efforts. The commercial manufacturers of the antigen have tried to solve the rapid agglutination tests for canine leptospirosis with only partial success. The author states that there is no effective vaccine, but Larson has produced what is considered an effective vaccine.

Q fever was reported by Army authorities in Italy and the Balkans. The Army had a sizeable outbreak of the disease in troops in Italy in 1945. The disease shows all characteristics of being world-wide; but the author reports the disease only in the United States and Australia.

In Chapter XXXI the author lists a number of diseases which have no reservoir in animals and in which animals have no part in the dissemination of the causative agent, among which are staphylococcus food poisoning. Brown of Johns Hopkins has incriminated staphylococcus mastitis as a cause of food poisoning in man.

The statement is made that *Fasciola hepatica* is not found in this country. The reviewer believes a few days in any large packing plant would correct the author's opinion about its incidence in the United States.

It is difficult to find any statement in the literature supporting the author's Table 62 statement that sheep are susceptible to *Brucella suis*. Sheep are not known to be infected very often in the United States with any of the *Brucella*.

There are occasional manuscript and proofreading errors which are to be regretted in a book of this type. Among items of note (ornithosis), page 229, item 7, the word pigeon no doubt is meant instead of parrot. On page 319, under item 11 *Coccidioidomycosis*, the word is "southwestern" instead of "southeastern." Mediastinal is mis-

spelled on page 317. "Variabilis" is misspelled in Table 46 on page 397. "Mansoni" is spelled "Masoni" on page 268. Little errors of this type distract the reader's attention.

A book of this kind is much needed in the respective fields of public health, human medicine, and veterinary medicine. The book points out very excellently by its omissions how little is known of many of the bacterial, rickettsial and virus diseases in animals. There is an important need for the study of animal epidemiology, bacteriology, and pathology in those diseases of animals which are communicable to man.

JAMES H. STEELE

The Louse. An account of the lice which infest man, their medical importance and control—By P. A. Buxton (2nd ed.) Baltimore: Williams & Wilkins, 1947. 164 pp. Price, \$3.25.

Professor Buxton's monograph on "The Louse" is clear, comprehensive, authoritative, and well illustrated. With this 2nd edition, the author has included references up to the end of 1945 and brought the subject as nearly up to date as was possible at that time. Illustrations have been added and the entire chapter on louse control has been rewritten.

The book is concerned with the lice which are parasitic on man. It covers their zoölogic position, anatomy, physiology, behavior, biology in relation to the host, and distribution on human beings. A chapter is devoted to the medical importance of *Pediculus humanus*, which not only covers the entomologic aspects of typhus, trench fever, and relapsing fever, but also gives an excellent discussion of the epidemiology of these diseases. The chapter on the control of lice will prove most interesting to those in the field of public health. The final chapter is devoted to the crab louse.

This little volume is highly recommended to entomologists, public health

workers, those interested in the epidemiology of infectious disease, and all others who enjoy a completely satisfactory volume on a single subject. W. A. DAVIS

Administration of Medical Care; Problems and Issues—By *Odin W. Anderson, Bureau of Public Health Economics, Research Series No. 2, Ann Arbor: School of Public Health, University of Michigan, 1947. 179 pp. Price, \$1.50.*

This book is an analysis and evaluation of the Medical-Dental Care Program in the State of Washington for the recipients of old age assistance.

The basic data on the services and costs of the program cover the period 1941–1945. Observations on the local characteristics of the program are based on ten selected counties.

Anderson's analysis ought to satisfy anyone who still doubts it that uncontrolled free-choice fee-for-service programs of medical care are destined to result in high costs, which, in turn, will produce either curtailment of services or limitation on fees. In Washington the legislature rebelled at the costs and abolished the program.

The acute problems of administration, finance, and standards of service are essentially the same whether the program is publicly or privately sponsored.

HOWARD M. KLINE

Health Practice Indices 1943-1946—*Prepared by the Subcommittee on State and Local Health Administration for the Committee on Administrative Practice of the A.P.H.A., 1947. 77 pp. Free.*

This new edition of *Health Practice Indices* summarizes data collected through evaluation schedules from 276 communities in 34 states, 1 territory, and 4 provinces of Canada. The data from any one community may be for any one of the years 1943 through 1946. If two or more schedules were submit-

ted the most recent one was used. It is estimated that the communities reporting have a total population of 26 million, representing some 30 per cent of those currently receiving full-time local health service.

The material is presented in a form familiar to many. There is a series of charts, each chart representing a particular community health resource or health activity. Each line on each chart represents one community's achievement. The lines on the charts are arranged so that the more favored communities are at the top, with the chart divided into quartiles, and any community may easily spot its position in relation to the reporting communities for any particular activity covered by the schedule. There is a list of the departments reporting, a tabular summary of the ranges, medians and quartiles, and a table of the relative standing of communities in each of the charts with communities designated by code numbers.

The volume is extremely valuable for the administrator, probably more so for the administrator who has completed an evaluation schedule than for one who has not. Completing one of the schedules is in itself good experience. The material is useful for self evaluation by an organization, for staff education, for program and budget planning, and for community organization. Other uses suggest themselves.

The evaluation schedules from which the charts are prepared have been kept up to date. New items are added from time to time or old ones are modified in accordance with current practices. Some might give rise to argument, for example the one on the ratio between population and the number of full-time clerks, but the indices have been carefully selected and are extremely reliable indicators of health resources and achievement. The Committee on Administrative Practice and its Subcommittee on State and Local Health Administra-

tion have done an excellent job in making this useful volume available.

WENDELL R. AMES

The American County—Patchwork of Boards—*By Edward W. Weidner. New York: National Municipal League, 1946. 24 pp. Price, \$35.*

This pamphlet adds to the mounting chorus of demand for the reorganization of local government in the United States. The examination of the various types of boards functioning in the more than 3,000 counties of the United States leads the author to suggest a manager system for counties. To achieve this would require changing the viewpoints of state and national officials, amending state laws and constitutions, eliminating special function boards and independently elected officers, and finally arousing the electorate to action. "A task of no small proportions," says the author, "but it can be, and is being done."

MARTHA LUGINBUHL

Rypins' Medical Licensure Examinations—*Prepared under the Editorial Direction of W. L. Bierring, M.D. with the Collaboration of a Review Panel. (6th ed.) Philadelphia: Lippincott, 1947. 690 pp. Price, \$6.00.*

The sixth edition of *Rypins Medical Licensure Examinations* has been published, as was the fifth edition, under the distinguished editorial direction of Dr. Walter Bierring, with the collaboration of a review panel of outstanding medical educators and clinicians. The text of the volume is now subdivided into two parts: Basic Medical Sciences and Clinical Sciences. Each area of knowledge such as anatomy, surgery, etc., is again covered in a chapter which contains a descriptive summary and a series of questions and answers.

The outstanding advances of the past few years in science and medicine, such as the work on the Rh factor, the latest concepts of various neoplastic diseases

and the antibiotics, have been incorporated in the text, which has been changed and added to in many places since the last edition.

For the first time, in this edition there is a chapter on psychiatry containing a glossary of psychiatric terms, a discussion of etiologic factors, syndromes and a review of therapeutic methods. The chapter on Hygiene and Preventive Medicine was revised under Dr. Charles F. McKhann's direction to include a discussion of public health administration, nutrition in public health, immunization programs, and mental hygiene. The personal foreword of the late Dr. Harold Rypins as contained in the first edition and a discussion of "The Philosophy of Examinations" by the present editor, both masterly treatises, are continued in the present edition.

FRANZISKA W. RACKER

Calcium and Phosphorus in Foods and Nutrition—*By Henry C. Sherman. New York: Columbia University Press, 1947. 176 pp. Price, \$2.75.*

The reading of any of Dr. Sherman's contributions to the field of nutrition is an enlightening and gratifying experience. This book is no exception. It is obviously the work of one who is thoroughly conversant with the vast literature on the subject, and one whose extensive investigations and mature thinking have contributed largely to present-day concepts of calcium and phosphorus requirements. The fields of animal and human experimentation are surveyed and the data critically analyzed and appraised. The conclusions presented are supported by abundant data and by sound reasoning.

This book should prove useful to teachers and workers in the field of nutrition and anyone seeking to understand the biological functions of calcium and phosphorus.

ERNESTINE BECKER MCCOLLUM

BRITISH JOURNAL OF SOCIAL MEDICINE

Among new periodicals of particular interest to experts in public health and preventive medicine in English speaking countries is the *British Journal of Social Medicine*, now at the beginning of its second year. It is a British Medical Association publication edited on behalf of the association by Drs. F. A. E. Crew, recently appointed Professor of Public Health and Social Medicine in Edinburgh, and Lancelot Hogben, head of the new department of Medical Statistics at Birmingham. Among other members of the editorial committee are Dr. Donald Hunter, Dr. Thomas McKeown, Dr. J. A. Ryle, and representatives of the Society of Medical Officers of Health. Dr. Donald Hunter is himself editor of the sister publication, the *British Journal of Industrial Medicine*, likewise issued quarterly by the B.M.A.

The primary objective of the two journals is to provide a medium for original research in all aspects of preventive medicine and cognate branches of social biology. Hitherto, there has been little encouragement in Great Britain for publication of papers embodying comprehensive numerical data; and the creation of the two journals should therefore act as a stimulus to neglected fields of research. As such the *British Journal of Social Medicine* does not offer a platform for controversial social opinions; but it invites well documented contributions of a factual character pertaining to the rôle of medicine in the organized community in addition to contributions on other themes to which it specifically refers in its notice to contributors. The *Notice to Contributors* states its terms of reference as follows:

‘As understood by those who are responsible for this *Journal*, social medicine is that branch of science which is

concerned with: (a) numerical, structural, and functional changes of human populations in their biological and medical aspects. To a large extent its methods must necessarily be statistical, involving the use of numerical data obtained either from official sources or from special field investigations, and interpreted in the light of established findings of the laboratory and of the clinic. Social medicine takes within its province the study of all environmental agencies, living and non-living, relevant to health and efficiency, also fertility and population genetics, norms and ranges of variation with respect to individual differences and, finally, investigations directed to the assessment of a regimen of positive health.”

Whole time departments of social medicine, of which there are now 5, and of industrial health 3, are a novel feature of the post-war set-up in British Medicine. In the early years of these new departments the *British Journal of Social Medicine* has had to draw heavily on the resources of medico statistical enquiry in the fighting services, but the editors anticipate an increasing measure of support from coöperation between departments of social medicine in the universities and regional public health authorities in the conduct of suitable investigations. Indeed such coöperation is already taking shape in some university centers. While, (as the title signifies), the *British Journal of Social Medicine* is in one sense a national publication, the problems which concern it are of world-wide interest. Accordingly, the editorial committee hope that it will be able to enlist the support of well established American departments and cordially invite their coöperation in assuring contributions of high quality, espe-

cially during the formative years of its existence.

"In expressing this hope the editors recognize that the rightful claims of preventive medicine in the medical cur-

riculum and in community life will gain prestige *pari passu* with an effective vindication of its contribution to the advancement of medical science in fields hitherto neglected."

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

"Must"-Paper-of-the-Month—Buy, beg or borrow this candid evaluation of dental caries control measures by a top-notch team of researchers and dentists. Only by iron self-control do I restrain myself from filling the rest of this bibliography section with excerpts from this not-to-be missed symposium. Whoever you are and whatever your job, you must read it and the four following papers by Volker, Arnold, Knutson, and Wisan. (Reprints at 6¢ from A.D.A.)

ANON. The Michigan Workshop on the Evaluation of Dental Caries Control Technics (and four related papers). *J. Am. Dent. A.* 36, 1:3 (Jan.), 1948.

Trained as a Group—Fast disappearing are the days when good intent could convert a physician into a health officer, an engineer into a public health engineer, or a nurse into a public health nurse. What the essential training should be is the burden of this brief but profound discourse. The author decries the segregation and isolationism still prevailing in graduate education. Public health is a coöperative enterprise, he says.

ANDERSON, G. W. Professional Training for Public Health. *Canad. Pub. Health J.* 39, 1:11 (Jan.), 1948.

Humor in Health—Realism stops you from putting your fingers in the buzz-saw by showing what happens if

you do. Humor corrects the state of mind that prompts you to put your fist in the saw. Somehow or other you should get your hands on this rare item, illustrated by some perfectly swell British posters drawn by the art editor of *Punch*.

BIRD, K. Propaganda Posters. *Health Education J.* 6, 1:9 (Jan.), 1948.

Unpleasant Thought for the Day—There is a tendency, these researchers allege, to implicate the staphylococcus as the cause of food poisoning when the usual pathogens are excluded. There may be other, and dirtier, culprits. Enteric streptococci were found the cause of four epidemics spread through canned milk, charlotte russe, barbecued beef, and ham bologna.

BUCHFINDER, L., et al. Studies in Enterococcal Food Poisoning. *Pub. Health Rep.* 63, 4:109 (Jan. 23), 1948.

This You'll Be Glad to Know—Residual effects of DDT louse powder last longer than the incubation period of the nits, so one application does the trick.

EDDY, G. W. The Treatment of Head Lice with MYL and DDT Louse Powders and the NBIN Emulsion. *Am. J. Hyg.* 47, 1:3 of (Jan.), 1948.

Good News—There are so many plus-minuses in this comparison.

white and non-white mortality trends that this "twice-burnt child" shies away from any comment—but he thinks it shows a more rapid decline in total mortality among the non-whites than the whites. If this is so, then it must give comfort to those health workers who have the Negroes' special health problems laid on their shoulders.

GOVER, M. Negro Mortality. Pub. Health Rep. 63, 7:201 (Feb. 13), 1948.

No Explanations Are Offered—Cancer appears to be more prevalent among diabetics than non-diabetics. The findings of this study suggest the need for more investigations into the association of chronic conditions.

JACOBSON, P. H. A Statistical Study of Cancer Among Diabetics. *Milbank Quart* 26, 1:90 (Jan.), 1948.

"Margarine Is a Good Source of Table Fat"—There is no growth factor present in butter that is not present in margarine and there is no longer much reason why health workers, too, shouldn't be heard in the demand for the repeal of discriminatory taxes and regulations against margarine.

LEICHENGER, H., *et al.* Margarine and the Growth of Children. *J.A.M.A.* 136, 6:388 (Feb.), 1948.

For Docile Minds—Here is a sentence for you to take to heart. "The relationship between hunger, famine, and infection has become more conspicuous by reiteration than by demonstration." It begins a report of a study which finds rats undergoing severe protein deprivation doing as well as adequately nourished controls against infection with *S. typhimurium*.

METCOFF, J., *et al.* Nutritional Status and Infection Response. *J. Lab. & Clin. Med.* 33, 1:47 (Jan.), 1948.

From Great Lakes Naval Barracks—Aggressive cleaning remains the most effective means of interrupting the pas-

sage of infective microorganisms from one barracks mate to another. Ultraviolet irradiation of floors and upper air helps, too. Though results were encouraging, the authors warn that they do not warrant the general installation of ultraviolet sterilizers.

MILLER, W. R., *et al.* Evaluation of Ultraviolet Radiation and Dust Control Measures in Control of Respiratory Disease at a Naval Training Center. *J. Infect. Dis.* 82, 1:86 (Jan.-Feb.), 1948.

Success Story—Good for young and old, the class as a teaching method can be adapted to any angle of the subject of nutrition. That we should use the group-guidance method more intensively is the burden of this paper. If the class is the preferred method for teaching nutrition, why isn't it equally good for other elements of the hygienic program, seems to be a fair question.

MURRAH, P. Teaching Nutrition. *Pub. Health Nurs.* 40, 2:66 (Feb.), 1948.

Modest but Promising—You'll be interested in this study in which volunteers inoculated subcutaneously with a cold virus grown on chick embryos, became refractory to intranasal inoculation with infective washings from an acquired cold. The writers do not pretend that all the answers are to be found in their limited work, but it is a suggestion of what can be done.

POLLARD, M., and CAPLOVITZ, C. D. Immunologic Studies With Common Cold Infection. *Am. J. Hyg.* 47, 1:106 (Jan.), 1948.

Words-of-One-Syllable Department—Though this is about therapeutics, not prevention of viral diseases, the paper is for you. Here is one quotation: "Question: Is it worth while giving antibiotics in the common cold or influenza? Answer: No."

RIVERS, T. M. Recent Advances in the Treatment of Viral and Rickettsial Diseases. *J.A.M.A.* 136, 5:291 (Jan. 31), 1948.

Since Lincoln's Day—Our national headache—protecting rural public health and providing medical care for the sticks—is an old but not a unique social malady. What other countries have done to relieve their difficulties in the same regions is reviewed. Many seem to be doing better than we are.

ROEMLER, M. I. Rural Health Programs in Different Nations. *Milbank Quart.* 26, 1:58 (Jan.), 1948.

You Can't Ring the Bell Every Time—Assuming that you want to know about failures as well as successes, here are two negative reports on tests of (1) an influenza A virus vaccine: 58 days after immunization an outbreak of influenza A occurred producing, among the immunized, a 20 per cent incidence and among the non-immunes an incidence of 27 per cent—scarcely enough higher to warrant the effort at prophylaxis; (2) in another school 54 per cent of the vaccinated (with a commercial influenza A and B vaccine) contracted influenza three months after treatment, whereas only 49 per cent of a smaller “unprotected” group came down with

the disease. Looks as though we haven't enough strains in our vaccines!

VAN RAVENSWAAY, A. C. Prophylactic Use of Influenza Virus Vaccine (and) Influenza A in a Vaccinated Population. *J.A.M.A.* 136, 7:435 (Feb. 14), 1948.

They Work, But—Those who didn't hear the paper at our Cleveland meeting will want to know about this study of multiple antigen prophylactics. Relative frequency of reactions should not discourage their use, is the conclusion, though parents should be warned that they do occur.

VOLK, V. K. Observations on the Safety of Multiple Antigen Preparations. *Am. J. Hyg.* 47, 1:53 (Jan.), 1948.

The Bad With the Good—Our highly productive chest x-ray programs have one undesirable effect: they send to sanatoria a few patients who haven't TB. Prompt sputum studies and the determination of tuberculin sensitivity can prevent these unfortunate tragedies.

WOODRUFF, C. E. On the Verification of the Diagnosis of Tuberculosis. *Pub. Health Rep.* 63, 6:184 (Feb. 6), 1948.

BOOKS RECEIVED

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING ,
AMERICAN PUBLIC HEALTH ASSOCIATION
BOSTON, MASS., NOVEMBER 8-12, 1948

STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS, NINTH EDITION — SEPARATES OF CHAPTER 2 ON MILK AND CREAM

The new edition of *Standard Methods for the Examination of Dairy Products* is expected to come from the press in late spring, 1948. The subject matter for guidance of administrators is largely assembled in Chapter 1 on Selection and Interpretation of Quality Tests. The subsequent Chapters, 2 to 13, supply directions for laboratory workers. This arrangement should not only cause less confusion for administrators but should make instructions clearer for the laboratory workers.

The fundamental laboratory procedures routinely used in the sanitary control of fluid milk are outlined in this edition in Chapter 2 on Microbiological Methods for Milk and Cream. In order that this instruction may be given col-

lege students taking course work in dairy bacteriology, and in order that copies of the official procedures, with particular reference to methods for determining the sanitary quality of milk and cream, may be available in less well financed public health laboratories, a small stock of Separates of Chapter 2 are being printed. The Separate will be bound in a durable paper cover.

The printing of Separates on Microbiological Methods for Milk and Cream is entirely on an experimental basis. If you are a prospective purchaser of these Separates, please notify the Association of your expected needs so an estimate of total requirements can be reached. The price will be nominal, based on the actual publication costs.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Robert M. Albrecht, M.D., Sand Lake, N. Y.,
Apprentice Epidemiologist, State Dept. of
Health

Henrik L. Blum, M.D., State Health Dept.,
760 Market St., San Francisco, Calif.,
Trainee for M.P.H.

C. L. Brumback, M.D., Box 536, Brighton,
Mich., Student, School of Public Health,
Univ. of Michigan

Orion R. Gregg, M.D., Choctaw-McCurtain
Health Dept., Hugo, Okla., Director

Edward J. Hagan, M.D., 222 Main St., Williston,
N. D., City Health Officer

Pillai M. Kunjukrishna, M.B., Public Health
Dept., Trivandrum, South India, Industrial
Medical and Hygiene Officer

Fred K. Laurentz, M.D., 1009 City Hall, 900
Brazos St., Houston, Tex., Director of Public
Health

Theodor Mueller, M.D., Gesundheitsamt,
Basle, Switzerland, Director of Public
Health Service

William J. Peebles, M.D., 112 Haralson St.,
LaGrange, Ga., Health Officer, Troup County
Health Dept.

Milton Silon, M.D., 907 Washington St., Hoboken,
N. J., Health Officer

Carl R. Trask, M.D., D.P.H., P. O. Box 77, Saint John, N. B., Canada, District Medical Health Officer

R. B. Turnbull, M.D., 304 East Main St., Gallatin, Tenn., Director, Summer Tuberculosis Control Dist., State Health Dept.

Miguel A. Ugarte-Machado, M.D., Arguelles 21, Maximo Gomez, Cuba, Public Health Officer

G. E. Duff Wilson, M.B., D.P.H., City Hall, Kitchener, Ont., Canada, Medical Officer of Health

Leonid Zavadsky, M.D., State Department of Public Health, Box 711, Sante Fe, N. M., Director, Tuberculosis Control Division

Laboratory Section

Juan J. Angulo, M.D., Luis Estevez 420, Santos Suarez, Havana, Cuba, Student, University of Michigan

Charles W. Darby, D.V.M., M.S., Disease Contraception Control Lab., Ralston Purina Co., St. Louis 2, Mo., Research Bacteriologist

Adelaide E. Evenson, Ph.D., University of Arizona, Tucson, Ariz., Asst. Professor, Department of Bacteriology

C. E. Fortenberry, 316 Graham St., Montgomery, Ala., Laboratory Technician, Dairy Producers Cooperative

Eleanore T. Hay, 3824 Bushnell Road, University Heights 18, Ohio, Serologist, Cleveland Division of Health

William H. Hay, No. 18 City Hall, Cleveland, Ohio, Chief of Laboratories, Cleveland Division of Health

Wilfred Lachance, M.D., St. Vallier Hospital, Chicoutimi, Que., Canada, Director of Laboratory

Beatrice D. Larner, 3726 N. Pinegrove, Chicago, Ill., Bacteriologist, Dept. of Milk and Water, State Department of Health

Pyung H. Lee, M.D., Bureau of Lab., State Health Dept., Lansing 4, Mich., Director, National Institute for Prevention of Infectious Diseases (Seoul, Korea)

Anna-May C. Loughery, 1720 Fourth Avenue, Los Angeles 6, Calif., Senior Student, Univ. of California

Herman K. Mohr, 24 East Columbia Avenue, Palisades Park, N. J., Bacteriologist, Schwarz Laboratories, Inc.

Harold E. Pearson, 344 State Office Bldg., Providence, R. I., Principal Serologist, State Dept. of Health

Sydney C. Rittenberg, Ph.D., 902 Tula Rosa Drive, Los Angeles 26, Calif., Asst. Professor of Bacteriology, Univ. of Southern California

Henry B. Schulhoff, M.Sc., 268 Handy Street, New Brunswick, N. J., Sanitary Engineer,

First Army Headquarters, Governors Island, New York

George A. Spendlove, M.D., M.A., U. S. Public Health Service, 605 Volunteer Bldg., Atlanta, Ga., Asst. Chief, Tuberculosis Evaluation Study

Eru Tanabe, 5182 Maple Avenue, St. Louis 13, Mo., Bacteriologist, St. Louis Health Dept.

Weldon C. White, M.D., Malaria Research Project, Box B, Seagoville, Tex., Senior Asst. Surgeon, U. S. Public Health Service

Vital Statistics Section

Ila D. Buck, Franklin, Tenn., In Charge of Clerical Training School, State Health Dept.

Loren E. Chancellor, 2323-47th, Des Moines, Iowa, Director, Division of Vital Statistics, State Dept. of Health

Lillian Konick, M.P.H., 610 George St., New Haven 11, Conn., Statistician, New Haven Dept. of Health

Regina Loewenstein, A.M., 1712-16th St., N. W., Washington 9, D. C., Chief, Operations Department, Study of Child Health Services, American Academy of Pediatrics

Engineering Section

John C. Bumstead, C.E., Engineering News-Record, 330 W. 42 St., New York 18, N. Y. Asst. Editor

George W. Burke, Jr., B.C.E., 613 Kennesaw Ave. N. E., Atlanta, Ga., Graduate Student of Sanitary Engineering, Georgia School of Technology

R. C. Burkhardt, P. O. Box 794, Huntsville, Ala., Principal Sanitarian, State Health Dept.

Robert T. Coleman, 700 Park Ave., Charlevoix, Mich., Sanitarian, District Health Dept.

James Covington, 429 McLemore St., Brownsville, Tenn., Senior Sanitarian, Haywood County Health Dept.

W. F. Drake, Fayetteville, Tenn., Senior Sanitarian, Lincoln County Health Dept.

William H. Gilmore, B.S.C.E., 1804 Goode St., Montgomery, Ala., Senior Public Health Engineer, State Health Dept.

Donald H. Helgren, M.P.H., 79 Bridge Rd., Ross, Calif., Sanitarian Consultant, State Dept. of Public Health

Earl McDonald, 22 Burke Terrace, Huntington, W. Va., Sanitarian, City Health Dept.

Erman A. Pearson, S.M., Box 80, Rt. 2, Bothell, Wash., Research Asst., Massachusetts Institute of Technology

Warren F. Smith, B.S.C.E., 5018 S. Benton, Kansas City, Mo., Asst. Public Health Engineer, City Health Dept.

Leo A. Sterenberg, B.C.E., 249 Troy Ave., Brooklyn 13, N. Y., Sanitarian, U. S. Public

Health Service Communicable Disease Center

John E. Taylor, State Health Dept., Little Rock, Ark., State Director, Communicable Disease Center Activities

Raymond F. Wagner, M.S., 55 Prospect St., Brookline, Mass., Sanitary Engineer, Brookline Health Dept.

314 State Capitol
Denver, Colo.

Fellowships for the Training of Health Educators

Fellowships leading to a Master's Degree in Public Health in the field of Health Education are again being offered this year to any qualified United States citizen between the ages of 22 and 40. Funds are available through a grant from the National Foundation for Infantile Paralysis.

Candidates must hold a Bachelor's degree from a recognized college or university at the time the application is filed, and must be able to meet the entrance requirements of the accredited school of public health of their choice. Proof of acceptance at such a school must be furnished before applications are submitted to the Fellowship Awards Committee for consideration. In addition to the Bachelor's degree, courses in the biological sciences, sociology, and education are required. Training in public speaking, journalism, psychology, and work in public health or a related field is considered desirable.

The fellowship consists of 8 or 9 months' academic work, which begins with the fall term in 1948, and three months of supervised field experience in community health education activities in a local health department. The academic training includes courses in public health administration, epidemiology, public health and school education, problems in health education, community organization, information techniques, and others.

Veterans are encouraged to apply, and will be paid the difference between their subsistence allowance under the G-I Bill of Rights and the monthly stipend of \$100 for single veterans or \$150 for married veterans. Employees of state or local health departments are not eligible, since federal grants-in-aid are provided through the states for such training.

Information and application blanks may be obtained by writing to the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

Public Health Workers Needed for European Rehabilitation Program

We need two qualified public health physicians; six public health registered nurses, one chief nurse to organize programs; one health consultant capable of setting up training schools for practical nurses; two nurse educators to head these schools; three medical social workers; and two public health dentists. All personnel must enlist for eighteen months. They must have physical stamina, be adaptable and sympathetic. A knowledge of Yiddish is necessary. Interested applicants should apply to the Health Committee of Joint Distribution Committee, 270 Madison Avenue, New York 16, N. Y.

POSITIONS WANTED

Senior Serologist seeks position in southern California; 15 years' experience including 4 years as laboratory officer. Major Army United States. Write Box L-1. Employment Service. A.P.H.A.

Veterinarian with training in bacteriology, organic chemistry, and pathology; experience in public health work as a veterinary inspector for large Midwestern city; experience in clinical laboratory procedures; desires position in or outside United States requiring initiative and diligence. Write Box V-1. Employment Service, A.P.H.A.

Position in School Health Education or public health education wanted by woman with many years' experience in teaching and community organization in public health. Master's degree in public health. East or Middle West preferred. Write Box H-E-1. Employment Service. A.P.H.A.

Biological and Physical Chemist available for research, control, teaching. Extensive experience research, industrial development and control on pharmaceuticals, biologicals, bio-assays, also expert in animal surgery. Original analytical and physical-chemical methods. Former University professor, 60 publications; many in medical research; books. Executive ability. Age 35, married, children. Seeks responsible position Hospital Laboratories or Educational Institution, New York Metropolitan area preferred. Box L-2. Employment Service. A.P.H.A.

Sanitary Engineer, A.B., M.S., C.E., 3 years' experience in Public Health Engineering with Federal, State, and local agencies. Army experience in water supply in the Pacific. Desires position in public health engineering. Write Box E-1. Employment Service. A.P.H.A.

Health Educator, B.S. in Education, New York University, M.P.H., Yale University Department of Public Health. Experienced in community organization with City Health Department; Instructor of Health Education in University. Interested in Health Education in the community or as School Health Coordinator. Write Box H-E-2. Employment Service. A.P.H.A.

Graduate Veterinarian with undergraduate and graduate work in dairy technology, experienced in both fields, desires position as sanitarian in a public health capacity or related work; suggestions solicited. Write Box V-2. Employment Service. A.P.H.A.

Physician 18 years of active practice in internal medicine and chest diseases (Pneumo-thorax treatment); desires position in tuberculosis control (institutional or field) or one requiring general clinical background. Eligible for New York license; available immediately; references sent on request; age 44, married, children. Write Box Ph-1. Employment Service. A.P.H.A.

Industrial Hygiene Chemist, M.S.; 13 years' experience in analytical chemistry. Seven years' experience with well known industrial hygiene laboratory. Familiar with wide variety of chemical methods.

Present salary above \$5,000 but immediate increase in salary not as important as opportunity to advance and reasonable security. Write Box I-H-1. Employment Service. A.P.H.A.

Academic position as Professor of Bacteriology or Preventive Medicine. Ph.D.;

M.D. expected in spring, 1948. Sixteen years' experience in teaching and research (7 years as Professor of Bacteriology). Many publications including textbook of bacteriology for medical students. Write Box Ph-2. Employment Service. A.P.H.A.

Opportunities Wanted

Bacteriologist; M.S., Ph.D. degrees, southern school; six years bacteriologist, public health department, two years head of department of bacteriology, small college; for further information, please write Burneice Larson, Director, The Medical Bureau, Palmolive Building, Chicago 11.

Health educator; Ph.D.; six years, health educator, nationally known organization; three years, health educator in industry; teaching experience; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health director; Ph.B., C.P.H., M.D. degrees; four years' experience as county health officer; three years' industrial experience (wartime assignment); now director of metropolitan department of health; for further information, please write Burneice Larson,

Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nursing administrator; Master's degree in public health; four years, industrial nursing consultant to public health agency; past several years, director of generalized state-wide program; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Young dentist; D.D.S., M.S. degrees; recently received Master's degree in Public Health; has done considerable research work on problem of dental caries; prefers public health dentistry or teaching position in pedodontia; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

ANNUAL MEETING OF THE NATIONAL HEALTH COUNCIL

Oscar Ewing, Federal Security Administrator, was the chief luncheon speaker at the annual meeting of the National Health Council in New York on February 17. He outlined some of the plans that have been made following President Truman's request to the Administrator to develop a 10 year program for improving the health of the nation.

Mr. Ewing told briefly of the plans for the National Health Assembly in Washington May 1-4 including a variety of voluntary and citizen agencies. The keynote of his address in this respect was that there were large areas of general agreement among the various groups interested in developing public health; that these areas should be exploited at the same time that discussions are going on with respect to health insurance about which there are large areas of disagreement.

The Federal Security Administrator also put forward a proposal for a plan of federal aid to medical education. He said that there is now a serious shortage of doctors, particularly in rural areas and among Negro populations, a deficiency which cannot be corrected for many years without some special aid. Mr. Ewing also used this occasion to announce the opening of Gallinger Hospital in Washington to the students of Howard University, thus making it the 13th hospital in the United States that is open to both Negro and white physicians.

Philip R. Mather, President of the Council, presided at the luncheon and Bailey B. Burritt, its Executive Director, made a brief report in which he presented the association with 8 chal-

lenges for the coming year, among which he cited the need for extending local full-time health service to the 40 million persons now without even minimum health protection in their local communities.

At the business meeting of the Council, the following officers were elected for the coming year:

President, Philip R. Mather
Vice-President, Ernest L. Stebbins, M.D.
Treasurer, Haven Emerson, M.D.
Assistant Treasurer, Franklin M. Foote, M.D.
Secretary, Reginald M. Atwater, M.D.

The business meeting also authorized an increase in the Board of Directors from 25 to 31 in order to give more representation to member agencies and to provide a wider geographic distribution of directors. Newly elected members of the Board of Directors are Bleecker Marquette of the Cincinnati Public Health Federation; Mrs. Brooks Potter, Newton, Mass.; Mrs. Lewis S. Thompson, Red Bank, N. J.; Anna Fillmore, Director of the National Organization of Public Health Nursing; Gale F. Johnston of the St. Louis Mercantile Commerce Bank Trust Company; and William P. Shepard, M.D., Metropolitan Life Insurance Company.

NEW ENGLAND HEALTH INSTITUTE, JUNE 16-18

The 1948 New England Health Institute will be held at the University of Massachusetts in Amherst, June 16-18. Among those on the program are Leonard A. Scheele, M.D., Surgeon-General of the U. S. Public Health Service; Martha M. Eliot, M.D., of Washington, Associate Chief of the U. S. Children's Bureau and President of the American Public Health Association; Ira V. Hiscock, Sc.D., of Yale University; V. A.

Van Volkenburgh, M.D., Assistant Commissioner of the New York State Department of Health; and Hugh R. Leavell, M.D., of Boston, Professor of Public Health Practice at the Harvard School of Public Health. One thousand local and state public health workers from the six New England states are expected to attend.

Meeting at the same time will be the local and state health workers of Massachusetts for the annual conference sponsored by the State Public Health Association and the State Department of Health. Vlado A. Getting, M.D., State Health Commissioner, heads the committee on arrangements for the joint meetings.

Arrangements for the housing and feeding of the gathering are being handled by Professor Ralph L. France, University of Massachusetts, Amherst. Programs will be mailed from his office in early May.

THE FOURTH INTERNATIONAL CONGRESSES ON TROPICAL MEDICINE AND MALARIA

Washington, D. C., May 10-18, 1948

The Fourth International Congress on Tropical Medicine and the Fourth International Congress on Malaria will meet jointly in Washington on the above dates under the sponsorship of the United States Government through its Department of State. Physicians, scientists, and other professional persons interested in tropical medicine are invited to attend as members; and students, non-professional persons interested in tropical medicine, and members of the families of professional members are invited to attend as associates. There will be a registration fee of \$10 for professional members who will receive the printed report of the *Proceedings of the Congresses*. Registration fee for associates is \$5 without the *Proceedings*, or \$10 with the *Proceedings*. Fur-

ther information concerning registration and hotel accommodations can be obtained by communicating with Dr. Wilbur A. Sawyer, Executive Secretary of the Congresses, Department of State, Washington 25, D. C.

The Congresses will hold both plenary and sectional meetings. The following sections have prepared programs.

1. Research and Teaching Institutes
2. Tropical Climatology and Physiology
3. Bacterial and Spirochetal Diseases
4. Virus and Rickettsial Diseases
5. Malaria
6. Helminthic Diseases
7. Protozoan Diseases
8. Nutritional Diseases of the Tropics
9. Tropical Dermatology and Mycology
10. Tropical Veterinary Medicine
11. Public Health
12. Medical and Veterinary Entomology

In addition, there will be two evening commemorative sessions, one on Wednesday, May 12, commemorating the establishment by Walter Reed of the mosquito transmission of yellow fever and celebrating his admission to the Hall of Fame, and one on Friday, May 14, commemorating the fiftieth anniversary of the discovery by Ronald Ross of the mosquito transmission of malaria. Opportunities will also be given to visit the Research Center of the Department of Agriculture at Beltsville, Md., the National Institute of Health, and the Naval Medical Research Center at Bethesda, Md., and the Army Medical Department Research and Graduate School in Washington. The tentative program of the Section on Public Health, of which Dr. Henry E. Meleney, Professor of Preventive Medicine, College of Medicine, New York University, is Convener, is as follows:

Session 1. Education and Research—Joint Meeting with Section on Research and Teaching Institutes

1. The Education of Public Health Personnel for Work in the Tropics. Angel de la Garza Brito, M.D.
2. Qualifications, Training and Opportuni-

ties for Public Health Nurses in the Tropics. Johanna Schwarte, R.N.

3. Plans and Purposes of the Institute for Scientific Research in Central Africa. L. Van den Berghe, M.D.

4. The Liberian Institute of the American Foundation for Tropical Medicine. Thomas T. Mackie, M.D.

Session 2. Research and Teaching—Joint Meeting with Section on Research and Teaching Institutes

1. Research and Training in Tropical Medicine in Europe. Dr. Oliver R. McCoy

2. Facilities for Research and Teaching in Tropical Medicine in Africa. Dr. Alexander F. Mahaffy

3. Research and Teaching in Tropical Medicine in the Far East. Dr. Marshall C. Balfour

4. Institutes for Research and Teaching in Tropical Medicine in the Americas. Dr. Morales Otero

5. Research and Training Institutes in Australia and the Southwest Pacific. Dr. A. H. Baldwin

Session 3. Health and Medical Services in the Tropics

1. Health and Medical Services for Agricultural Workers in the Tropics. Edward I. Salisbury, M.D.

2. Health and Medical Services for Rural Populations in Brazil. Paulo C. A. Antunes, M.D.

3. Health and Medical Services in the Tropics for a Colonial Population. Professor Jerome Rodhain

4. Health and Medical Services for the Southwest Pacific. Sir Raphael Cilento

5. The Contribution of Christian Medical Missions to the Practice of Medicine in the Tropics. Dr. Harold G. Anderson

Session 4. The Tuberculosis Problem in the Tropics

1. Tuberculosis in Jamaica. Richard A. Cory, M.D.

2. Tuberculosis in South Africa. Dr. B. A. Dormer

3. Tuberculosis in India. Dr. A. C. Ukil

4. BCG Vaccination in the Control of Tuberculosis. Dr. Joseph D. Aaronson

5. Pulmonary Calcification in Relation to Tuberculosis and Fungus Infections. Amos Christie, M.D.

Session 5. Public Health and Vital Statistics Problems

1. Population Problems in the Tropics. Dr. T. Lynn Smith

2. Vital Statistics Problems of India. K.C.K.E. Raja.

3. China's Public Health Problems. P. Z. King, M.D.

4. The Work of the Interim Commission of the World Health Organization. Dr. Frank A. Calderone

ANNUAL MEETING OF THE PUERTO RICO PUBLIC HEALTH ASSOCIATION

The 7th Annual Meeting of the Puerto Rico Public Health Association was held in San Juan, February 10 to 13, under the Presidency of Guillermo Arbona, M.D., M.P.H., at the School of Tropical Medicine. Ten sessions were organized for the discussion of public health problems important to the island, including stream pollution, housing sanitation, milk sanitation, Blue Cross programs, airport sanitation, communicable disease control, public health nursing, personnel problems, the federal hospital plan, coöperation with voluntary health agencies, the island nutrition program and plans for mental hygiene.

Participants from Puerto Rico included Oscar Costa Mandry, M.D., E. Garrido Morales, M.D., Maria S. Lacot, Ramon A. Rios, M.D., Rafael Timothee, M.D., Sarah R. Chacon and Angel M. Marchand, M.D., M.P.H.

The Secretary of the Association is Mr. Nelson Biaggi, Sanitary Engineer, of the staff of the School of Tropical Medicine.

Visitors from the mainland at the meeting included Professor C.-E. A. Winslow, Editor, *American Journal of Public Health*, who conducted an institute during the program; Estella Ford Warner, M.D., States Relations Division, U. S. Public Health Service, Washington, D. C.; Robert S. Breed, Ph.D. of Geneva, N. Y.; Harold W. Brown, M.D., Columbia University School of Public Health; E. J. Herring, Senior Sanitary Engineer, U. S. Public Health Service, New York, N. Y.; W. W. Peter, M.D., Institute of Inter-American Affairs, Washington, D. C.; John L. Rice, M.D., New York,

N. Y. and Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.

New officers of the Puerto Rico Public Health Association include:

President—Rafael A. Timothee, M.D., Rio Piedras

President-elect—Juan A. Pons, M.D., Santurce

Vice-President—Americo Pomales, Ph.D., San Juan

Secretary—Nelson Biaggi, San Juan

Sub-Secretary—Rafaela Salgado de Rosado, Santurce

Treasurer—Angeles Cebollero, San Juan

Representative on A.P.H.A. Governing Council—Guillermo Arbona, M.D.

DR. MARY CROSSE RECEIVES ORDER OF BRITISH EMPIRE

V. Mary Crosse, M.D., of the Public Health Department, Birmingham, England, was made an Officer of the Order of the British Empire in the King's New Year Honors List in recognition of her work on the care of premature babies.

Readers of the *Journal* will recall that Dr. Crosse was a member of an A.P.H.A. team of speakers which visited several state and public health meetings during the spring of 1947 and attended also the Western Branch A.P.H.A. meeting. Dr. Crosse is the author of a widely read text on the care of the premature baby which she is now revising.

AWARD TO PSYCHIATRIC AIDE OF THE YEAR

The first recipient of the annual National Mental Health Foundation's Psychiatric Aide of the Year Award of \$500 was recently made to Walter Starnes of the Winter Veterans Administration Hospital of Topeka, Kans. In commenting on the award, Karl A. Menninger, Manager of the hospital, praised the Mental Health Foundation for calling the attention of the public to a group of persons whose service is rendered far away from the public eye. Said he, "Walter Starnes is an ambassador extraordinary. The qualities for which he was chosen—kindness,

tact, sensitivity to the needs and feelings of others, patience, humility, and, above all, character—could very well make Starnes the outstanding man of the year."

Nominees for the award were selected from among 12,000 psychiatric aides by the staffs and patients in private and public mental hospitals throughout the country. Five additional candidates were cited for honorable mention and each received a \$50 award.

FEDERAL SECURITY ADMINISTRATOR'S HEALTH ASSEMBLY

Federal Security Administrator Oscar R. Ewing has called a National Health Assembly to meet in Washington, May 1-4. The purpose of this Assembly is to help develop a ten year health program for the nation. It grew out of President Truman's recent request to Administrator Ewing to develop plans for the next ten years in public health.

Twenty-four national leaders have been invited to serve on the conference executive committee. Among these is Abel Wolman, Chairman of the Association's Executive Committee, and Louis I. Dublin, its Treasurer. The list includes representatives of newspapers, radio, and motion pictures; farm, labor, and business groups; as well as professional organizations.

The activity of the Assembly will be in the form of panel discussions each of which will explore in detail a specific phase of the health problem. Not all of the panel leaders have been chosen but the one on local health units will be under the chairmanship of Haven Emerson, M.D., the Chairman of the Association's Subcommittee on Local Health Units.

In announcing the Assembly, Mr. Ewing said, "Health is the people's job. We can have national action only to the extent that we have community interest and action. As I see it, the job is: to know accurately the health facili-

ties and personnel of each community and of the nation, to determine our health deficits or the difference between what we need and what we have, and to devise feasible methods of meeting these deficits. I hope that, in the real sense of the word, this Assembly will spring from and its results go back to the 'grass roots' of the country."

PHILIP R. MATHER PRESIDENT OF
AMERICAN SOCIAL HYGIENE
ASSOCIATION

At the Annual Meeting of the American Social Hygiene Association in New York on February 4, Philip R. Mather of Boston was presented with the William Freeman Snow Medal for Distinguished Service to Humanity and was elected President of the Association. The citation reads:

To Philip Richard Mather . . .

Who from boyhood was taught by the precepts and examples of his distinguished father and mother the obligations and the satisfactions of social service . . .

Whose imperative sense of duty causes him never to hesitate to sacrifice personal comfort and convenience in favor of an opportunity to aid a worthy cause . . .

Who served with honor in the armed forces of his country in wartime . . .

Whose sound judgment and perspicacity have made him a valued member of the governing bodies of many local, state and national welfare agencies . . .

Who has given generously of his resources to relieve suffering and correct injustice . . .

Whose courtesy, humor, modesty and unselfishness have endeared him to all who know him . . .

Who embodies in himself the traits of the true philanthropist—"one who desires to do good to all mankind" . . .

The American Social Hygiene Association is proud to award the William Freeman Snow Medal for Distinguished Service to Humanity.

Mr. Mather has been President of the National Health Council since 1946.

At this meeting also Edward S. Godfrey, Jr., M.D., recently retired as Commissioner of Health of New York

State, received Honorary Life Membership in the Association.

One of the interesting sessions of the meeting was the panel discussion on Marriage and Family Life in Universities Under the G.I. Bill of Rights in which four G.I. students and their wives were the discussants and Howard W. Ennes, Jr., Chief of the Extension and Training Section, Venereal Disease Division of the U. S. Public Health Service, was Moderator. At the same session, Charlotte Carr, Executive Director of the Citizens' Committee on Children of New York City, in an address, "Building a City for Families," suggested the integration of social and welfare services through the development of local community centers, pointing out the confusion and inefficiency of having separate community buildings for police, welfare, health and many others.

PTA AND LOCAL HEALTH UNITS

Recent activities of the National Congress of Parents and Teachers have encouraged the coverage of the entire nation with local health departments under competent full-time professional leadership. This is the project of the Association's Subcommittee on Local Health Units which began rather than ended with its 1945 report, *Local Health Units for the Nation*, and which has had numerous chain reactions, among the most important being the Ann Arbor and Princeton Conferences.

The National Congress of Parents and Teachers has recently taken two important steps to further the development of local health departments. It sponsored S. 2189 in the national Congress. This bill, introduced on a bipartisan basis by Senators Saltonstall (Mass.) and Hill (Ala.) on February 20, provides for grants-in-aid to states for the specific purpose of developing or extending local health departments. As in the Hill-Burton Hospital Con-

struction Act, aid to a state would be contingent upon the preparation by the state health department of an overall plan for serving the entire state with local health units of such population and area as to be efficient and economical. This bill has the approval of the State and Territorial Health Officers Association. It will be actively pushed by many of the citizen agencies represented at the Princeton Conference both as groups and as individual members.

A second activity of PTA is its Health Conference of February 16 and 17 in Chicago. Present were the organization's state chairmen, and particularly the health chairmen. They represented some 27,000 local chapters aggregating a membership of five million. These state chairmen heard: How to Organize for Securing Public Support from members of four effective state health committees—Florence R. Sabin, M.D., E. L. Wittenborn, H. C. Cranford, and Hugh W. Breneman, respectively of Colorado, Illinois, North Carolina, and Michigan. They discussed national and state legislation and made their campaign plans for S-2189; they learned something about evaluating local health services and they reserved a morning to detailing what they as an organized body could do to extend public health services.

NEW PRESIDENT OF NATIONAL COMMITTEE FOR MENTAL HYGIENE

Arthur H. Ruggles, M.D., Superintendent of the Butler State Hospital, Providence, R. I., was recently elected President of the National Committee for Mental Hygiene, succeeding Eugene Meyer, publisher of the *Washington Post*. Dr. Ruggles is Consultant in Mental Hygiene and Lecturer in Psychiatry at Yale University, Consultant to the U. S. Public Health Service, and former President of the American Psychiatric Association. Mr. Meyer resigned when he was appointed Presi-

dent of the International Bank for Reconstruction and Development.

In order to distribute leadership further among both lay and professional members, the National Committee for Mental Hygiene has replaced its former Executive Committee of 5 members with a new Board of Directors of 15; the old Board of Directors of 31 members has been replaced with a council of 51 members.

MULTIPLE SCLEROSIS SURVEYS

The January *AARMS Forward*, the year old organ of the Association for the Advancement of Research in Multiple Sclerosis, reports on the development of the area surveys that have been approved by the Association's Medical Board. Such statistical surveys in local areas of not less than half a million population in representative regions of the United States will develop background data as a ground work for a systematic attack on Multiple Sclerosis. The first survey is being made of Metropolitan New York and will soon be completed.

Statistical surveys are also being made in England and Europe through special grants received for that purpose.

AMA RURAL HEALTH CONFERENCE

The American Medical Association held its annual National Conference on Rural Health in Chicago on February 6 and 7. Among the speakers were Florence R. Sabin, M.D., Health and Welfare Commissioner of Denver, and G. F. Moench, M.D., Hillsdale County, Michigan, Health Officer and Health Chairman of the National Congress of Parents and Teachers. They emphasized that the 40,000,000 persons in the United States who do not have a full-time local health officer are mostly in rural regions.

This Conference was held in coöperation with the American Academy of Pediatrics which for the past 2 years

has been studying the child health services throughout the country. John P. Hubbard, M.D., who is Director of the Academy study, reported on findings up to date and reinforced the other speakers as to the gaps in rural health services.

HERE AND THERE IN CEREBRAL PALSY

The following news about the facilities for the care of cerebral palsy victims is summarized from various sources:

The 28th annual meeting of the Ohio Society for Crippled Children in October appropriated \$15,000 for special training in cerebral palsy for doctors, physical therapists, and speech therapists.

In Grand Rapids, Mich., a nursery for cerebral palsied children was recently established to provide treatment for both in- and outpatients. The Junior League of Grand Rapids assisted in this project.

In North Dakota, the first cerebral palsy demonstration clinic to be held in the state was held in Jamestown on December 1 and 2, under the sponsorship of the North Dakota Chapter of the National Society for Crippled Children, the North Dakota Medical Association, and the Crippled Children's Services of the North Dakota Public Welfare.

In Mississippi, a hospital school for cerebral palsied children was recently opened at Jackson Charity Hospital which has set aside 20 beds for children from all sections of the state. The medical expenses of this hospital school will be borne by the Crippled Children's Service of the State Department of Education.

In New York, a center partially financed from state funds for the care and treatment of cerebral palsy patients was recently opened at LeRoy, Genesee County. The new center, a joint project of the University of Rochester and the

State Department of Health, offers diagnostic treatment and hospital services for patients as well as facilities for personnel training and research. In New York City, a cerebral palsy preschool training center has been opened at Lenox Hill Hospital. It is being financed by the New York State Association for Crippled Children.

The women's national sorority, Alpha Gamma Delta, recently voted to sponsor a project on a national basis for the cerebral palsied. The tentative plans include funds for films and information services with other specific fields of work to be chosen at a later date.

FUND FOR TRAINING IN ATOM MEDICINE

Late in January, the U. S. Atomic Energy Commission set up a million dollar fellowship fund to train doctors and biologists in the new field of atomic science. This fund will be spent to carry out the first year of a program to relieve "the serious shortage of trained scientific personnel in the field of atomic energy as applied to biology and medicine."

Although treatment of atomic bomb victims will be explored, the primary aim is to gain more basic scientific knowledge of both the good and bad effects of atomic radiation on living organisms.

The program will be administered by the National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

DOCTOR HARPER DAY IN WISCONSIN

On January 31, public health workers in Wisconsin celebrated Doctor Harper Day in honor of C. A. Harper, M.D., who at the age of 84 retired from the Wisconsin State Health Department after 47 years of service, 39 of them as State Health Officer. Speakers on the occasion, which also commemorated public health progress in Wisconsin, were Thurman B. Rice, M.D., Professor of Public Health, Indiana University, on

"Where We Came From in Public Health"; Floyd C. Beelman, M.D., Kansas State Health Officer on "Where We Are in Public Health"; and William D. Stovall, M.D., Director, State Laboratory of Hygiene on "Where We Are Headed in Public Health." The presiding officer at this session was Carl N. Neupert, M.D., who succeeded Dr. Harper as Wisconsin State Health Officer in 1943.

At the banquet session, Gunnar Gundersen, M.D., President of the Wisconsin State Board of Health, was master of ceremonies, and Harry S. Mustard, M.D., New York City Health Commissioner, made the main address on "The Development of State and Local Health Services."

STUDY OF WAR'S EFFECT ON CHILDREN

Under the provisions of the National Mental Health Act, and on recommendation of the National Advisory Mental Health Council, a research grant of \$20,000 has been made to the International Committee on Mental Hygiene for a study of the effect of war on children.

The study is under the direction of David Levy, M.D., Professor of Psychiatry at Columbia University, who will present the findings at the International Congress on Mental Health in London in August, 1948.

TRAINING RURAL DOCTORS

A plan has recently been announced in Illinois for financing medical education for farm boys. This joint plan of the Illinois Medical Society and the Illinois Agricultural Association makes available a revolving fund of \$100,000 as loans to students wishing to prepare for rural medical practice. In accepting the loan, the student must agree to return to a town of less than 5,000 population in his home county and practise general medicine. He is expected to repay the loan in 5 annual payments after he begins to practise medicine, at 2 per

cent interest. If his agreement is not kept, the interest is 7 per cent.

Under the plan at present, 4 new students can be accepted annually. The program is administered by a Farmer and Doctor Loan Fund Board made up of 3 representatives from each of the 2 sponsoring agencies.

JUNIOR CHAMBER OF COMMERCE AWARD TO DR. HINGSON

On January 21, in a ceremony at Chattanooga, Tenn., Surgeon R. A. Hingson of the U. S. Public Health Service was presented with a gold key as a token of honor by Harold E. Stassen for the U. S. Junior Chamber of Commerce. This group annually selects 10 outstanding young men to receive this honor. Dr. Hingson won this award for his part in developing caudal analgesia and also the Hypospray technique for parenteral injections which he was the first to use.

A number of the other Junior Chamber of Commerce awards are of interest to public health workers: Lavon Peterson, blind founder of a School of Engineering for the Blind in Omaha, Neb.; the mayors, respectively, of New Orleans and Denver, DeLesseps Morrison and James Quigg Newton, Jr., the latter of whom had a great part in the reorganization of the Denver public health services; Dr. Glenn Seaborg, the nuclear chemist; and Adrian Sanford Fisher, counselor to the Atomic Energy Commission; Cord Meyer, Jr., the young veteran who is President of United World Federalists. Others are Thomas Reid, human relations expert of Baltimore, and Congressmen Richard Nixon and Glenn Davis of California and Wisconsin respectively.

GRANTS FOR RESEARCH IN ORAL CANCER

The National Cancer Institute has for the first time made available funds to dental schools to finance the study of oral cancer. Awards of nearly \$45,000

to 9 major dental colleges were recently made by the National Advisory Cancer Council "for the most part to pay the salaries of instructors who will teach early recognition of cancer of the mouth to dental students."

Medical authorities agree that in a large percentage of mouth cancer cases, the dentist is in the best position to recognize the disease in its earliest stages. The 9 dental colleges receiving grants are located in 7 states.

SERVICE AWARD TO SALLY LUCAS JEAN

The 1948 state service award of the New York State Association for Health, Physical Education and Recreation was recently presented to Sally Lucas Jean, Consultant in Health Education of the National Foundation for Infantile Paralysis.

DEATH OF RALPH E. TARBETT

Ralph Edwin Tarbett, Sanitary Engineer Director (Ret.), U. S. Public Health Service, died at the U. S. Marine Hospital, Baltimore, on January 23, following a heart attack. Recognized as an outstanding public health engineering authority in the United States, Mr. Tarbett had a 34 year career with the U. S. Public Health Service, having been appointed as the first sanitary engineer of the Service in 1913.

Mr. Tarbett has been deeply interested in stream pollution measures, was engaged in yellow fever prevention along the United States-Mexican border in the 20's, was Chief Sanitary Engineer of the Public Health Service Sanitation program following an outbreak of typhoid due to contaminated oysters, in 1945 was on the Public Health Service Board sent to Japan to study the medical and public health aspects of strategic bombing, and in 1946 directed the environmental aspects of the Cook County (Ill.) Public Health Survey.

Mr. Tarbett has been a member of the American Public Health Association

since 1928, and a Fellow since 1930. He was referee for the Committee on Professional Education for its reports on professional qualifications of public health engineers. He was the author of numerous technical articles and reports dealing with various phases of public health engineering.

PHARMACEUTICAL-MEDICAL RESEARCH FOUNDATION

The formation of the Pharmaceutical-Medical Research Foundation to make extensive studies relating to the chemical and physical changes that occur in tissues and to the physiology of the body was recently announced in the *Journal of the American Medical Association*. This is a joint effort of the pharmaceutical and medical professions. Devoted to scientific research, it will be supported in major part by the pharmaceutical industry, but it will be wholly a public institution in purpose, conduct, and service. Much of its initial basic research will be in the field of degenerative diseases.

The chairman of the committee which includes representatives both of the pharmaceutical industry and the medical profession that was organized to establish the new foundation, is R. L. Sensenich, M.D., President-elect of the American Medical Association.

DEMONSTRATION MENTAL HEALTH CLINIC

Psychiatric service will be offered to all residents of Prince Georges County, Maryland, with a population of about 140,000, at a demonstration mental health clinic recently opened. This is the first of such demonstration clinics to be organized by the U. S. Public Health Service and will be operated jointly by the Service and the Maryland State Department of Health.

Mabel Ross, M.D., child psychiatrist, formerly with the Johns Hopkins Hospital, is in charge of the clinic.

NEW YORK STATE FELLOWSHIPS IN PUBLIC HEALTH

Fellowships are available in New York State for young physicians interested in public health as a career. The Fellowships, which carry a stipend of \$3,600 per year, are for a period of 2 years or less, depending upon the qualifications of the applicant. Both field training and academic training are given. Tuition at a school of public health as well as necessary travel and other expenses are paid.

Further information may be obtained from Franklyn B. Amos, M.D., New York State Department of Health, State Office Building, Albany 1.

PROJECTS APPROVED FOR A THIRD OF HOSPITAL CONSTRUCTION FUNDS

As of January 9, the U. S. Public Health Service announced the approval of 92 applications for construction of hospitals, dispensaries, and health centers under the Hill-Burton Survey and Construction Act. The total estimated cost of these 92 projects is nearly 41 million dollars, of which one-third will be a charge against federal funds. The projects are in 10 states and largely in rural areas.

With the approval of these projects, 36 per cent of the \$1,125,000,000 in both federal and local funds contemplated by the Act, has been pledged.

NATIONAL ADVISORY CANCER COUNCIL

Early in January, Edward A. Doisy, M.D., of the St. Louis University School of Medicine, and John J. Morton, Jr., M.D., of the University of Rochester (N. Y.) School of Medicine, were added to the National Advisory Cancer Council of the National Cancer Institute. Dr. Doisy, a Nobel prize winner in Medicine in 1943, about 25 years ago first isolated *theelin* which led the way to the production of synthetic hormones. He is also responsible for the isolation and the later artificial production of vitamin

K which saved many new-born babies who would otherwise have died of hemorrhagic disease, and is at present working on antibiotics related to penicillin and streptomycin.

Dr. Morton, a distinguished surgeon and former President of the American Cancer Society has, through basic research, advanced the study of hormones and diseases of the colon.

NURSING IS FOR MEN TOO

The American Nurses Association, in a recent news release, calls attention to the vocational possibilities of nursing for men high school graduates. It points out that wartime experiences of the army and navy corpsmen amply proved that nursing is not a career for women alone. Further, men are especially well fitted for work in heavy industry and in hospitals with large divisions caring for orthopedic conditions. Although the number of men admitted to nursing schools increased from 45 in 1945 to 334 in 1947, there is still room for many more men students.

NATIONAL MALARIA SOCIETY

The 30th annual meeting of the National Malaria Society was held with the American Society of Tropical Medicine and the American Academy of Tropical Medicine in Atlanta, Ga., in December. The following officers were elected for 1948:

President—E. Harold Hinman, M.D., Wilson Dam, Ala.

President-Elect—Dr. Wendell Gingrich, Galveston, Tex.

Vice-President—Nelson H. Rector, Atlanta, Ga.

Director—E. L. Bishop, M.D., Chattanooga, Tenn. (for a four-year term)

Editor—Frederick L. Knowles, Memphis, Tenn.

Secretary-Treasurer—Martin D. Young, Sc.D., Columbia, S. C.

NEW YORK'S STATE REGIONS

Announcement has recently been made of the organization of the 6 New York

State health regions, and the appointment of the regional health officers. These regional offices will provide consultation for existing local health departments and will help in the development of local health units in the counties that do not now have them. They will also assist in program planning and with emergency assistance.

Five regions serve the area outside of New York City; the regions are made up of from 6 to 17 counties and range in population from 866,000 to one and two-thirds millions. The sixth region serves New York City. The regional health officers and their headquarters are as follows:

Buffalo—Archibald S. Dean, M.D., who has been serving as one of the former state district health officers and most recently assigned to the Buffalo area.

Rochester—Joseph P. Garen, M.D., who has most recently been state district health officer in Rochester.

Syracuse—Ray D. Champlin, M.D., who has recently been state district health officer in Oneonta.

Albany—Ralph M. Vincent, M.D., who was district health officer of the Binghamton area.

New York (for the suburban area)—Robert L. Vought, M.D., who has been district health officer in Saranac Lake.

New York (for the five counties of New York City)—Philip J. Raffle, M.D., who has already served for several years as the district health officer for the area suburban to New York City.

All are members of the American Public Health Association.

WEST VIRGINIA COUNTY STUDIES INTEGRATION OF NEW HEALTH ACTIVITIES

As the province of public health has broadened to encompass such functions as nutrition, mental health, dental health, chronic disease control, hospital planning, and medical care administration, a reëxamination of basic administrative procedures has become increasingly necessary. An effort will be made in Monongalia County and Morgan-

town, West Virginia, to develop a program including these newer fields of public health. It is not to be considered, however, as a "demonstration project" of a model public health program. As much as possible the program will be developed through local and state resources, aided by no more federal subsidy for operating personnel than other counties enjoy.

Opportunities are provided for close relationships between the Health Department and the Monongalia Memorial Hospital as well as the University of West Virginia, with its two year Medical School and its School of Social Work.

The U. S. Public Health Service is assigning Milton I. Roemer, M.D., of the States Relations Division, as Director of the Monongalia County Health Department, to work in an experimental spirit, with plans to loan statistical personnel for concurrent studies of the program. Dr. Roemer will attempt an evaluation of the administrative problems involved in providing a comprehensive scope of public health services at the county level. It is hoped that information may be gained which will be of value as local health units are extended throughout the country, especially if they are faced with new responsibilities in the administration of medical services.

F. C. BISHOPP, PH.D., RECEIVES BRITISH AWARD

The British Embassy in Washington recently announced the awarding of His Majesty's Medal for Service in the Cause of Freedom to F. C. Bishopp, Ph.D., "in recognition of the valuable service you rendered to the Allied war effort in various fields of scientific research and development." Dr. Bishopp was active in the development of insecticides and equipment for the use of the military forces in combating malaria and other insect-borne diseases. At present he is assistant chief of the Bureau

of Entomology and Plant Quarantine in the U. S. Department of Agriculture.

A.W.W.A. ELECTS HONORARY MEMBERS

Abel Wolman, Dr. Eng., Chairman of the Executive Board of the A.P.H.A., and Louis R. Howson, C.E., were two of the three men elected to honorary Membership in the American Water Works Association in January, 1948. Dr. Wolman has been a member of the A.W.W.A. since 1918, and was President in 1943. Mr. Howson has been a member since 1916, and was President in 1942.

In electing Dr. Wolman to Honorary Membership, he was characterized as "a leader in the thought and practice of public health engineering." Mr. Howson was described as "a student of the economics of water supply who shares his knowledge freely with the water works industry."

CONFERENCE ON PUBLIC HEALTH STATISTICS

A Conference on Public Health Statistics will be held at the University of Michigan School of Public Health, Ann Arbor, June 14-18. Co-sponsor of the conference is the Association of State and Territorial Health Officers which formally approved the project at its Washington meeting in December.

The conference will discuss a pattern for the flow of statistical data from local to state and federal official health agencies so that they may be used effectively as administrative tools and as means of evaluating both local and state public health programs. The lecture and group discussion method will prevail.

Guests of the conference will be state health officers, directors of local health administration, directors of statistics, and a small sampling of local health officers from each state.

Among the faculty members are: Halbert L. Dunn, M.D., Chief of the Office

of Vital Statistics, U. S. Public Health Service; Marjorie T. Bellows, M.S.P.H., Statistician of the American Heart Association; W. Thurber Fales, Sc.D., Director of Statistics, Baltimore Health Department; and Ruth Puffer, Dr. P.H., Director of Statistical Service, Tennessee Department of Public Health.

ENGLISH TUBERCULOSIS ASSOCIATION ADOPTS JOURNAL

Word has been received from the Tuberculosis Association of England that it has adopted the journal *Tubercle* as its official organ. The January, 1948, issue of the journal was the first published under the terms of the merger.

PERSONALS

Central

WENDELL C. ANDERSON, M.D.,† recently became Director of Cancer Control of the Indiana State Department of Health. He was formerly one of the district directors of the Department but most recently has been doing postgraduate work in cancer control in Roswell Park Memorial Hospital, Buffalo, N. Y.

HARRY BECKER,† has become Director of the International UAW-CIO Social Security Department with offices in Detroit, Mich., where he will be in charge of developing a health and medical care program for the Union's members together with various social security benefits. He has been most recently Consultant in Medical Care Administration and Director of Administrative Methods Unit, Division of Health Services, U. S. Children's Bureau, Washington, D. C.

HARRY M. GUILFORD, M.D.,† Epidemiologist of the Wisconsin State Health Department since 1921, retired on January 31. He will continue to make his home in Madison.

ALICE HEATH,* Peoria, Ill., Health Department, has recently been appointed

Senior Health Education Consultant, Public Health Education Section, Washington State Department of Health.

HERMAN C. MASON, Ph.D.,* Chicago, Ill., has been appointed adviser to the Korean National Laboratories Seoul, Korea, Civil Affairs Division, Department of the Army.

CHANGES IN MINNEAPOLIS, MINN., CITY HEALTH DEPARTMENT

HELEN HESTAD was appointed Maternal and Child Health Nursing Consultant in the Bureau of Public Health Nursing. She was formerly Assistant Director in the Minneapolis Community Health Service.

GRACE HENSHAW BABCOCK was appointed as Mental Hygiene Consultant in the Bureau of Public Health Nursing. Mrs. Babcock was for a number of years Mental Hygiene Consultant, with voluntary public health nursing agencies in Minneapolis.

Eastern

MANFRED BOWDITCH,† formerly Director of the Division of Occupational Hygiene of the Massachusetts Department of Labor and Industries, has been appointed Director of Health and Safety of the Lead Industries Association with headquarters at 420 Lexington Avenue, New York, N. Y.

FRANCIS B. CARROLL, M.D.,* former Assistant Director of Medical Services, Veterans Administration, Boston, Mass., has been appointed to the position of Medical Director.

HERBERT M. DECKER,† Sanitary Engineer, has joined the research staff of Insect Control and Research, Inc., Baltimore, Md., which provides entomology and sanitation consultant service in food plants in Maryland and vicinity. Mr. Decker was formerly with the National Canners Association, New York, N. Y. and dur-

ing the war served overseas as an officer in the U. S. Army Sanitary Corps.

LOUIS K. DIAMOND, M.D., noted authority on Hematology and Assistant Professor of Pediatrics at Harvard Medical School, Boston, Mass., has been appointed technical director of the American Red Cross National Blood Program, Washington, D. C.

LOUISA ESKRIDGE,* on February 16 joined the staff of the Public Charities Association of Philadelphia, Pa., as Secretary of its newly created division of Public Health. She has most recently been a health education consultant with the U. S. Public Health Service assigned to District 3, Chicago, Ill.

NICHOLAS J. FIUMARA, M.D., M.P.H.,† former Navy Medical Officer has been appointed Director of the Division of Venereal Diseases of the Massachusetts Department of Public Health. Dr. Fiumara came to the State Health Department in 1941 as an Assistant Epidemiologist prior to his present appointment and was promoted successively to Assistant Health Officer and Health Officer.

GENERAL PAUL R. HAWLEY, retiring Medical Director of the Veterans' Administration, was guest of honor at a banquet given by the National Council on Rehabilitation in the Waldorf Astoria, New York, N. Y., on March 19. He was selected for this honor because his "reorganization of Medical Services on which the physical restoration of the disabled veteran is based, constitutes a unique contribution to the field of rehabilitation."

HUGO V. HULLERMAN, M.D.,* will take over his duties on May 1 as Assistant Director of Rhode Island Hospital in Providence, a voluntary general 500 bed hospital that serves annually more than 10,000 patients. Since

* Fellow A.P.H.A.

† Member A.P.H.A.

1944 Dr. Hullerman has been Assistant Director of the American Hospital Association. He also has administrative public health experience on both state and local levels.

CYRUS H. MAXWELL, M.D.,† on March 3 became Chief of Administration of School and College Health Service in the United States Office of Education. He had since 1937 been chief of the Bureau of Health Service in the New York State Education Department. Dr. Maxwell is President-Elect of the American School Health Association.

WADE W. OLIVER, M.D.,* began his new duties as Associate Director of the Division of Medical Sciences of the Rockefeller Foundation, New York, N. Y., on March 1. He retired as Professor of Bacteriology, Long Island College of Medicine, New York, N. Y., after 31 years of training young physicians. In his new work he will assist in the placement of doctors from all over the world coming to the United States for study under Foundation fellowships and scholarships.

HOWARD E. SEYMOUR, former associate, Personnel Service, National Tuberculosis Association, New York, N. Y., was named acting director of the Service following the recent resignation of V. J. SALLAK.† At the same time, Miss SELMA B. GERMOND, former consultant for rehabilitation training, was named as associate.

KENNETH D. WIDDEMER,* has resigned as Acting Executive Director of the Health Council of Greater New York and AUBREY MALLACH,† Associate Director, is temporarily responsible for administration of the Council.

Southern

T. PAUL HANEY, M.D.,* assumed duties as Director of Pinellas County Health Department, with headquarters in St. Petersburg, Fla., on Janu-

ary 5. He was formerly Director of Maternal and Child Health of the Florida State Health Department.

CHANGES IN FLORIDA STATE HEALTH DEPARTMENT:

ELIZABETH REED, R.N.† has been named Acting Director of the Division of Health Information.

L. L. CLARK, D.D.S., has been appointed Director of the Bureau of Dental Health. He was formerly doing both private and public health dental practice in Indiana.

J. E. SCATTERDAY, D.V.M., has been appointed to the newly created position of Public Health Veterinarian. He was formerly employed by the Alachua County Health Department, Gainesville, Fla.

H. J. DARCY,† Director of the Bureau of Sanitary Engineering of the Oklahoma State Health Department, received the 1948 Kenneth Allen Award of the National Federation of Sewage Works Associations on January 28 at a meeting of the Oklahoma Water and Sewage Conference in Stillwater. Presented every 3 years, the award is for "outstanding service in the sewerage and sewage treatment works field."

FRED J. WAMPLER, M.D.,* who has been a District Health Officer in the Virginia State Board of Health with offices in Luray, has resigned to accept appointment as Chief of Field Party for the Institute of Inter-American Affairs and has been assigned to Lima, Peru, where his address is in care of the American Embassy.

HOWARD M. KLINE, Ph.D.,† is serving as General Secretary of the National Conference on Health Goals to be held in Washington, D. C., May 1-4 under the auspices of the Federal Security Administration. He is on a

* Fellow A.P.H.A.

† Member A.P.H.A.

3 months leave from the American Public Health Association of whose Subcommittee on Medical Care he is the technical secretary.

Western

PAUL BALLINGER, R.S., has been appointed Director of the Bureau of Sanitation for the Los Angeles County Health Department. For the past 10 years Mr. Ballinger has been assistant to H. A. YOUNG, R.S., Director of the Bureau, who recently retired.

MILTON P. DUFFY,† Chief of the Bureau of Food and Drugs, California State Department of Public Health, has been granted a leave of absence to accept an appointment as expert consultant on the staff of General Douglas MacArthur in Japan.

HARRY S. JORDAN, has been appointed Junior Sanitary Engineer in the Sanitary Engineering Division of the Arizona Health Department. He has spent the last 5 years in the U. S. Army.

GORDON M. PARROTT, M.D., has recently been appointed Medical Health Officer in the City of Tacoma Health Department, Wash., serving as Assistant to the Director of Health, C. R. FARGHER, M.D.*

Other Areas

OSCAR FELSENFELD, M.D., who has been working on research on *Salmonellae* at the School of Tropical Medicine, San Juan, Puerto Rico, has accepted the newly created position of Director of Bacteriology at Cook County Hospital, Chicago, Ill.

Death

MARSHALL WILLIAM MEYER, M.D.,* Health Commissioner of Madison, Wis., died on January 22 in his office of a heart attack at the age of 46.

Before assuming the Madison Commissionership in November, 1947, he had been first District Health Officer and then Venereal Disease Control Officer of the Wisconsin State Board of Health, which he first joined in 1939 after several years of private practice both in Chicago and Wisconsin.

Developments in the Use of the Newer Organic Insecticides of Public Health Importance*

JUSTIN M. ANDREWS, Sc.D., F.A.P.H.A., AND
S. W. SIMMONS, Ph.D.

Scientist Director, Deputy Officer in Charge, and Senior Scientist, Chief, Technical Development Division, Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga.

IN June, 1946, Bishopp¹ reviewed comprehensively in this *Journal* the position of DDT in the control of insects of medical importance. His resumé covered the literature through most of 1945 and part of 1946. Since then, reports of experience with this compound have multiplied exceedingly. To them have been added numerous accounts of other insecticides, the accomplishments of which have been popularly represented in some instances as surpassing even the most fantastic predictions made about DDT. Without attempting to review minutely the formidable array of scientific and popular contributions concerning all of these substances, the following notes compend the characteristics of some of the more important insect killing chemicals having significance in public health practice.

For relatively exhaustive compilations

of insecticides, their diluents, and adjuvant chemicals, the following sources should be consulted. The first volume of Frear's *Catalogue of Insecticides and Fungicides*, published in 1947, deals exclusively with chemical insecticides.²

It lists the official names and formulas of several thousand chemical compounds, condensation products, and miscellaneous substances alleged to have insecticidal properties. Information is summarized concerning their synonyms, the organisms against which insecticidal tests have been made and results obtained, together with author references. The seventh edition of *Entoma*,³ also published in 1947, is an assembly of general information about insecticides and fungicides, their diluents, spreaders, penetrants, adhesives, etc., together with rosters of their trade names and the industrial sources from which these chemicals can be obtained. Cupples' list of *Proprietary Surface-active Agents of Possible Use in Insecticidal Prepara-*

* Special Review Article, prepared at the request of the Editorial Board

tions⁴ contains the commercial names and sources of insecticidal accessories, their physical properties, industrial uses, chemical composition, and the purposes for which they are suitable (i.e., emulsifier, detergent, wetting agent, etc.). This very useful summary was released by the U. S. Department of Agriculture in 1943 and merits revision. The *Blue Book* for 1947,⁵ issued by the publishers of *Soap and Sanitary Chemicals*, is an up-to-date listing of industrial sources for insecticides and associated chemicals.

There is at present no officially authorized procedure for designating non-proprietary names of insecticides for general use. The complex nature of these substances makes the use of exact chemical names impracticable and undesirable for this purpose. The only existing basis for the acceptance of generic names or designations is voluntary compliance with suggested practice on the part of governmental, professional, and commercial interests. This is time-consuming at best and is not always successful in the long run. In the meantime, it permits the entry into the literature of abbreviated laboratory designations, such as initials or accession numbers, or multiple trade names for the same compound. In later years, these may be difficult to identify with generic names in current use. The Interdepartmental Committee on Pest Control* has taken the initiative in promoting the standard usage of non-proprietary names of insecticides, rodenticides, etc., by recommending "common" names or designations to be defined and registered with the U. S. Patent Office to preempt their use as trade-mark names. Other

organizations having legitimate concern with this problem are the American Chemical Society, the American Association of Economic Entomologists, the American Medical Association, and the American Veterinary Medical Association. As far as possible, the names of insecticides used in this review are those endorsed by the Interdepartmental Committee. Important laboratory or trade synonyms are shown in footnotes.

DDT *

Shortly after Dr. Bishopp's article¹ appeared, a comprehensive review of *DDT and Other Insecticides and Repellents Developed for the Armed Forces*² was published by the U. S. Department of Agriculture. Since then the literature on DDT has continued to pyramid though much of it is concerned with problems of little immediate interest to public health or with refinements and further details on uses that had been suggested previously. Two semi-popular books have been published on DDT.^{7,8}

From the public health standpoint in this country, the most important development during the past two years has been the accumulation of vast practical knowledge in the use of DDT in civilian malaria control programs. During the calendar years 1945, 1946, and 1947, nearly 3.2 millions of house-spraying applications were made in rural areas or small towns in over 300 counties by the health departments of 13 states in coöperation with the U. S. Public Health Service. The average number of sprayings per house varied from nearly two in 1945 to not quite one and one-half in 1947, when 875,534 different houses were treated.⁹ This

* Composed of representatives from the Bureau of Entomology and Plant Quarantine of the Agricultural Research Administration and the Insecticidal Division of the Production and Marketing Administration (both of the U. S. Department of Agriculture), the U. S. Public Health Service, and the Food and Drug Administration (both of the Federal Security Agency), the Fish and Wildlife Service of the U. S. Department of the Interior, the Army, and the Navy.

* This seems to be the universally accepted designation for the various mixtures of the para-para and ortho-para isomers of dichloro-diphenyl-trichloroethane used as insecticides. The laboratory designation, *SPLY*, used by the Orlando Laboratory of the USDA Bureau of Entomology and Plant Quarantine, and the trade names *Gesarol* and *Nrocid* have appeared in previous literature. The initials *GNBA*, gesarol neocide base, American, have also been used.

extensive experience has produced basically standardized operational procedures¹⁰ with some regional variations as to the number, extent, and DDT content of the applications per year.^{11,12} The rate generally recommended in this country for indoor residual application against mosquitoes and flies remains, as in 1945,¹ 200 mg. per sq. ft.¹³⁻¹⁶ (one gal. of 5 per cent DDT mixture per 1,000 sq. ft.) of treated surface. Highly satisfactory anopheline control has been obtained for the entire season in unoccupied houses in southeastern Georgia with a single application of 200 mg. of DDT on walls, ceilings, and the backs and undersides of furniture.¹⁵

The insecticidal effectiveness and durability of DDT on various types of surfaces have been studied in reference to *Anopheles quadrimaculatus*,^{14, 17,18} the principal malaria vector east of the Great Divide, and house flies, *Musca domestica*.^{16, 19} In general, the results were similar though house flies were found slightly more susceptible to DDT than were anopheline mosquitoes¹⁶; the females of both were more resistant than the males.^{14, 16} Under laboratory conditions, residual effectiveness was lost faster when treated surfaces were exposed to house flies than to the same number of mosquitoes due, presumably, to the numerous body deposits of the house flies.¹⁶ Smoke and grease deposits also interfered with the effectiveness of DDT.¹⁸

Rough surfaces, as unplanned wood, wallpaper, wall-board, natural fabrics, pitted metal, etc., remained highly lethal for 6 months or more¹⁹; smooth surfaces, as glass, tile, plexiglass, etc., failed to retain toxic films of DDT for as long a period. Freshly shellacked or painted wood, linoleum, dried mud, cement, new metal screen, synthetic fabrics, etc., gave very inferior results.^{17, 18} The penetration of DDT into woods of various types and the effects of DDT concentration and the

volatility of solvents on the recoverability of DDT from sprayed wood surfaces have been studied.²⁰

There appeared to be little difference in effectiveness between the same concentrations of oil-borne and water-emulsified DDT¹⁷ though in native huts (thatched roof, mud walls) in India, the emulsion was preferable.²¹ Water-wettable DDT showed definite superiority to DDT-xylene deposits on cement, and better results on new metal and glass. The former product deteriorated faster on outside than interior surfaces.¹⁷

DDT was removed or denatured by dry-cleaning, paste wallpaper cleaner, ironing with a hot flat-iron, and vigorous brushing.¹⁷ It was reduced slightly by the first vacuum cleaning but not by subsequent cleanings. It was not removed to any great extent by sponging with soap and water or by light dusting.

Standard practices have been developed in the application of DDT as an anopheline larvicide.²² A method of using as little as 0.05 lb.²³ of DDT per acre dissolved in one gallon of fuel oil and applied as a mist from a hand-operated compressed-air sprayer was shown to be effective in controlling malaria mosquitoes and was more efficient and economical than any of the older larviciding techniques.²³⁻²⁵

Perhaps the most important recent development in the use of DDT in disease prevention is its extensive and successful use in the control of endemic or murine typhus fever by reducing rat flea populations.^{26, 27} Detailed procedures for this purpose have been developed.^{28, 29} During the last 3 years, these have been applied on a large scale by various state health departments in coöperation with the U. S. Public Health Service. Their use has been associated with significant reductions in the numbers of reported human cases of murine typhus fever, the incidence of rats positive for typhus complement-fixation, and the occurrence of the oriental rat flea,

Xenopsylla cheopis.³⁰ DDT is less effective against rat mites and lice than against *X. cheopis*.³¹

Practical methods of application have also been developed for use of DDT in the control of house flies³² and of blow flies.³³ DDT is relatively ineffective as a larvicide against these two types of flies and thus is used chiefly against the resting adults. It follows that determination of their normal resting habits and application of the spray in accordance with this information is essential to successful control. These publications emphasize the point that DDT should not be used as a substitute for adequate sanitary measures, particularly around food handling establishments.

Thoroughness of application to insure the deposit of DDT in resting places is also stressed in the control of cockroaches.* Stenborg³⁴ suggests DDT in a combination of a spray and a dust for this purpose, though the use of chlordane has gained wide favor in the control of these insects.

Residual sprays of DDT have been used with great success in the control of sandflies of the genus *Phlebotomus* in Italy,³⁵ Palestine,³⁶ and Peru.³⁷ This gives great hope for the prevention of sandfly-transmitted diseases such as dermal and visceral leishmaniasis, bartonellosis, sandfly fever, etc.

Thompson has shown that residual deposits of DDT are lethal to the common species of scorpion in the West Indies.³⁸

During 1946, and especially in 1947, there were widespread complaints that DDT was less effective than it had been

during the first year of general use. Investigations of some of them³⁹ indicated that they were concerned almost entirely with flies—not mosquitoes—even though the DDT applications had been directed against malaria mosquitoes instead of flies. Poor sanitation resulting in high levels of fly production was directly responsible for some of these conditions. It is believed that many of the complaints were largely psychological, deriving from a decreased tolerance to even small numbers of flies caused by a year or more of relative freedom from large numbers of flies as a result of the early applications of DDT.

Strains of *Musca domestica* shown to be naturally resistant to DDT have been reported from Italy.⁴⁰ It has been shown possible by laboratory exposure to DDT space sprays to develop a strain of house flies abnormally resistant to DDT,⁴¹ and the strain thus isolated was also unusually resistant to chlordane, pyrethrum and rotenone.⁴² It is concluded that the method of selection developed an unusually strong stock of flies rather than one having a specific resistance to DDT. To what extent this phenomenon entered into the basis for the complaints against DDT in the southeastern states during late 1946 and 1947 is not known.

Recent papers have adduced evidence suggesting that the contact repellency of residual DDT may be as important as its insecticidal qualities in reducing the numbers of *Anopheles maculipennis atroparvus*,⁴³ *Aedes aegypti*,⁴³ *Anopheles gambiae*,⁴⁴ and *Culex tarsalis*,^{45, 46} on sprayed resting places. It appeared in some instances,⁴⁴⁻⁴⁶ that mosquitoes may even engorge themselves within treated premises, avoiding lethal contact with sprayed surfaces, and survive the experience apparently unharmed. The implications of these observations are not in harmony with conclusions from previous work with *A. quadrimaculatus*^{47, 48} or *A. gambiae*.⁴⁹ If confirmed,

* Data on the effect of modern insecticides on cockroaches, bedbugs, ants, ticks, mites, and scorpions are included even though the species mentioned are not of established significance in the transmission of human diseases. Their behavior in association with man and the proved vectorial propensities of certain related species suggests that these arthropods may have increasing public health importance—and useful information concerning their wide-scale destruction is all too meager.

TABLE 1
DDT solubility in representative solvents

| Solvent | DDT Capacity (gm./100 ml. solvent at 30° C.) | Flash Point (°C.) | Specific Gravity (at 20° C.) | Color |
|--|--|----------------------|---------------------------------|-------------------------------|
| Cyclohexanone | 100-120 ²¹ | 44° ⁷ | 0.948 ²¹ | Water-white to pale yellow |
| Benzene | 77- 83 ²¹ | -8° ⁷ | 0.879 ²¹ | Water white |
| Methyl Chloride (under pressure) | 60- 70 ²¹ | | | |
| Velsicol A R 50 Mono- and dimethyl Naphthalenes | 65- 70 ²¹ | 109° ²¹ | 0.995 ²¹ | Yellow |
| Velsicol N R 70 Polymethylnaphthalenes | approx. 65 ²¹ | 127° ²¹ | 1.03 ²¹ | Green-black |
| Toluene | 60- 65 ²¹ | 7° ²² | 0.864 ²¹ | Water-white |
| Xylene | approx. 60 ²¹ | 23° ²² | 0.857 ²¹ | Water-white |
| Acetone | 50- 66 ²¹ | -17° ²² | 0.791 ²¹ | Water-white |
| No. 2 Fuel Oil | approx. 10 ²¹ | | | Tan |
| Cottonseed Oil | approx. 9 ²¹ | | | Straw |
| Kerosene | approx. 8 ²¹ | | | Water-white |
| 95% Ethyl Alcohol | approx. 1.5 ²¹ | | 0.809 ²¹ | Water-white |
| Freon | less than 2 ²¹ | | | |

they will occasion a basic revision of present beliefs regarding the mode of action of DDT against mosquitoes and possibly other insects.

Solvents for DDT—Much of the early application of DDT as a larvicide and as an adulticide was made with the petroleum oils as solvents. Under World War II military field conditions, this presented no great logistical problem as kerosene and fuel oil were widely distributed due to their extensive uses for other purposes. However, the solubility of DDT in these products is relatively limited (see Table I). For economical application under civilian conditions, it was necessary to have carriers which held larger amounts of DDT per unit volume to reduce transportation and handling costs and to permit increased coverage per unit weight from airplanes, power sprayers, and even hand sprayers.

Thus, solvents were sought and tested for high DDT-dissolving capacities, coupled with such other essential qualities as high flash point to reduce fire hazards; proper physical characteristics for optimal droplet size; low toxicity to man, useful animals, and vegetation; non-corrosiveness to equipment and sprayed surfaces; freedom from inhibiting reactivity with DDT; non-

repellency to insects; exemption from tendencies to bleach, stain, or to extract underlying color; and minimal residual odor or other components.

Gunther,⁵⁰ Jones, *et al.*,⁵¹ have conducted extensive tests on more than 100 candidate solvents. They have published solubility data and have listed various physical properties of the more practical and economical solvents. In general, the DDT solvents may be classified on a strictly chemical basis as follows:

1. *Aliphatic hydrocarbons*, consisting of the crude oils and petroleum derivatives. These hold relatively small concentrations of DDT.

2. *Aromatic hydrocarbons*, chiefly velsicols, xylene, cyclohexanone, and naphthas. These are high capacity solvents.

3. *Chlorinated hydrocarbons*, exemplified by ortho-dichlorobenzene and trichloroethylene. These are more variable but in general carry large quantities of DDT.

4. *Liquefied gases*, comprising the "freons," dimethyl ether and others. These are low capacity solvents; their use frequently requires auxiliary solvents of high DDT-carrying ability.

5. *Vegetable oils*, such as sesame oil, castor oil, cottonseed oil, etc. These vary in their dissolving capacity, even among different batches; in general, they are poor solvents for DDT.

6. *Miscellaneous organic solvents*, of which alcohols, ethers, and ketones are of importance. They have variable capacities for DDT.

In cow manure infested with known numbers of house-fly larvae, 1 per cent BHC-xylene emulsion (0.1 per cent gamma) or 5 per cent BHC dust (0.5 per cent gamma) at 400 mg. BHC per sq. ft. prevented 90 per cent of flies from emerging.⁷¹ Fifty per cent emergence of adults occurred from mash media treated with BHC at 8 p.p.m.; DDT at 77 p.p.m.; thiourea, 81 p.p.m.; and borax, 92 p.p.m., respectively.⁹⁰ LD 95 was obtained against third-instar house-fly larvae with the incorporation of 15.3 mg. of gamma isomer per liter of artificial media. Second-instar larvae were more susceptible and pupae much more resistant. BHC was non-toxic to eggs but did kill the emerging larvae.⁹¹

BHC has been shown to be highly toxic⁸¹ to adult flies and, where odor is not a factor, shows promise for their control.^{82, 92} The knock down with BHC is more rapid than with DDT and residual action is equally effective over a period of several weeks.⁹² In laboratory tests, direct spray applications as low as 0.25 per cent BHC killed all adult flies.⁸⁴

BHC-xylene emulsions (0.5 per cent) were highly effective against the prepupal stage of the blowfly, *Lucilia cuprina*.⁹³

A 1 per cent dust applied against head lice caused complete immobilization in 20 minutes.⁸⁴ Against the body louse, BHC dust was more effective than either DDT or DDD.⁶⁷ In other tests with the body louse, 50 per cent were killed with 0.016 mg. of the gamma isomer per gm. of insect body weight as against equivalent kills with 0.30 mg. of p: p'-DDT per gm. of insect body weight.⁹⁴

A 1 per cent solution of 10 per cent gamma BHC in fuel oil, sprayed on open fields showed good control of the American dog tick.⁸⁵ Against the lone-star tick, *Amblyomma americanum*, effective control has been obtained with a 5 per cent dust rubbed into the hair of dogs. The action was slow, 12 to 14

hours being required to kill; feeding was stopped within 2 hours.⁹⁶ Dipping cattle in a 0.5 per cent solution of 50 per cent wettable BHC (10 to 13 per cent gamma isomer) gave protection against this parasite for 7 to 10 days.⁹⁷ In oil base preparations and water suspensions, BHC at 0.005 per cent gamma isomer killed adult females of an arsenic-resistant tick, *Boophilus discoloratus*.⁹⁸

Fleas, *Ctenocephalides canis*, were controlled in 4 hours' time with a 5 per cent BHC dust rubbed into the hair of dogs. Little or no residual action was indicated, however, as reinfestation occurred in 3 to 4 days even though an odor of BHC remained.⁹⁶

Against the bedbug, BHC has shown a high degree of toxicity⁸¹ and has given more effective control than several other insecticides tried, including DDD and DDT.⁶⁷

Roaches (*Periplaneta americana*, *Blatta germanica* and *Supella supellae-tillum*) were controlled in 5 room houses by 250 ml. of BHC dust containing 10 per cent of the gamma isomer. They were affected in 1 hour and killed in 12 hours, but residual effectiveness was limited; the eggs of the roaches were not injured.⁹⁹ Crude dusts containing 0.5 and 1.0 per cent BHC have killed high proportions of roaches, *P. americana*, with the 1.0 per cent dust driving the roaches out of cracks.⁸⁴

Snails of the genera *Planorbis* and *Bulinus*, intermediate hosts of *Schistosoma*, were controlled in laboratory and field tests within 24 hours by dust containing 5-6 p.p.m. of gamma BHC.¹⁰⁰

CHLORINATED CAMPHENE

Chlorinated camphene, with the approximate empirical formula $C_{10}H_7Cl_3$, contains 67-69 per cent chlorine.^{101, 102}

Chlorinated camphene is a colorless, odorless, non-volatile liquid, insoluble in water, soluble in most organic solvents. It is stable to heat and light, and does not oxidize or polymerize. It is a powerful insecticide, effective against a wide range of insects, including beetles, flies, and mosquitoes. It is particularly effective against the house fly, *Musca domestica*, and the common house mosquito, *Culex pipiens*. It is also effective against the American dog tick, *Amblyomma americanum*, and the lone-star tick, *Amblyomma americanum*.

during the first few weeks following application, but declined much more rapidly in effectiveness. Chlordane exerts a relatively strong fumigant action against adult house flies and *A. quadrimaculatus* mosquitoes; its early effectiveness as a residual spray may be due largely to this property.⁷⁰

BENZENE HEXACHLORIDE *

Benzene hexachloride (1, 2, 3, 4, 5, 6-hexachlorocyclohexane), with an empirical formula of $C_6H_6Cl_6$, is a complex of 5 known isomers. The gamma isomer is the principal insecticidal ingredient, the alpha and beta isomers have some toxicity, and the delta and epsilon isomers are relatively non-toxic.⁷⁰⁻⁸² The commercial form is a light buff-to-tan colored powder having a persistent musty odor arising from small amounts of manufacturing impurities. BHC is chemically stable except in the presence of alkalis. It is insoluble in water but readily soluble in a wide range of common organic solvents.

The value of BHC was first reported by Slade⁸³ in 1945 and later by O'Kane and his associates⁸⁴ working independently. The toxic action of BHC against insects may be as a contact poison, as a stomach poison, as a fumigant, or as a combination of any of the three. The value of BHC as a fumigant has been shown against the German cockroach and other insects and the use of small amounts of this chemical allowed the content of other agents to be reduced as much as 50 per cent.⁸⁵

When oil sprays of BHC were applied to vegetation or surfaces such as mud or plaster walls there was considerable loss of effectiveness from absorption of the toxicant. Wettable powder formulations minimized this loss considerably.⁸⁶

Adult mosquitoes have been shown to

be susceptible to BHC.⁸¹ A kerosene solution containing 0.04 per cent gamma isomer controlled all anophelines, especially *A. culicifacies*, in India.⁸² In laboratory tests with *A. quadrimaculatus* adults, 5 per cent BHC (30 per cent gamma) applied at 200 mg. per sq. ft. effected lethal results comparable to the same amount of DDT for a period of 8 weeks.⁶⁵ The residual durability of BHC is limited as the compound is lost by evaporation; increased dosage is not likely to extend its effectiveness beyond 10 weeks. BHC was equally effective against *A. minimus*, *A. vagus* and culicines in field tests.^{21, 87} The paralytic action of BHC is said to be more rapid than either that of DDT or chlordane.⁶⁰ *Aedes aegypti* mosquitoes are reported⁸⁸ to have died after feeding on rabbits which received 25 mg. per kg. of gamma isomer 2 to 4 days before.*

As a mosquito larvicide, BHC at concentrations of 0.1 p.p.m. and 0.05 p.p.m. held in check larvae and pupae, respectively, of *Culiseta incidens*. In comparison, 0.5 p.p.m. solutions of DDT and DDD were effective against both larvae and pupae.⁶⁴ At 0.1 p.p.m., BHC controlled fourth-instar larvae of *A. quadrimaculatus*.^{60, 89} In field tests, one application of 10 lbs. per acre of a 0.5 per cent gamma isomer dust gave complete control of *Aedes* spp. larvae.⁸⁴

* Since the above was written, an article by E. F. Knipling, R. C. Bushland, S. H. Babers, G. H. Culpepper, and E. S. Raun entitled "Evaluation of Selected Insecticides and Drugs as Chemotherapeutic Agents Against External Blood-Sucking Parasites" was published in the *Journal of Parasitology* (34:55-71, 1948). The authors have tested the effect of 33 chemicals, most of them effective insecticides, administered internally to rabbits sometimes at lethal dosages, against one or more of the following ectoparasites fed subsequently on the treated rabbits: body lice (*Pediculus humanus corporis*), yellow fever mosquitoes (*Aedes aegypti*), ear mites (*Psoroptes equi* var. *cuniculi*), and the lone star tick (*Amblyomma americanum*). Gamma-benzene hexachloride, chlordane, chlorinated camphene, dicumaryl, sabadilla seed, chloromethyl *p*-chlorophenyl sulphone, and certain of the 3-indandione compounds. Of these, benzene hexachloride was most toxic to mosquitoes and ear mites and certain of the indandiones to lice.

* Also known as BHC, 666, and, especially in British literature, as Gammaxane, a trade name.

during the first few weeks following application, but declined much more rapidly in effectiveness. Chlordane exerts a relatively strong fumigant action against adult house flies and *A. quadrimaculatus* mosquitoes; its early effectiveness as a residual spray may be due largely to this property.⁷⁰

BENZENE HEXACHLORIDE *

Benzene hexachloride (1, 2, 3, 4, 5, 6-hexachlorocyclohexane), with an empirical formula of $C_6H_6Cl_6$, is a complex of 5 known isomers. In cow manure infested with known numbers of house-fly larvae, 1 per cent BHC-xylene emulsion (0.1 per cent gamma) or 5 per cent BHC dust (0.5 per cent gamma) at 400 mg. BHC per sq. ft. prevented 90 per cent of flies from emerging.⁷¹ Fifty per cent emergence of adults occurred from mash media treated with BHC at 8 p.p.m.; DDT at 77 p.p.m.; thiourea, 81 p.p.m.; and borax, 92 p.p.m., respectively.⁹⁰ LD 95 was obtained against third-instar house-fly larvae with the incorporation of 15.3 mg. of gamma isomer per liter of artificial media. Second-instar larvae were more susceptible and pupae much more resistant. BHC was non-toxic to eggs but did kill the emerging larvae.⁹¹

BHC has been shown to be highly toxic⁸¹ to adult flies and, where odor is not a factor, shows promise for their control.^{82, 92} The knock down with BHC is more rapid than with DDT and residual action is equally effective over a period of several weeks.⁹² In laboratory tests, direct spray applications as low as 0.25 per cent BHC killed all adult flies.⁸⁴

BHC-xylene emulsions (0.5 per cent) were highly effective against the prepupal stage of the blowfly, *Lucilia cuprina*.⁹³

A 1 per cent dust applied against head lice caused complete immobilization in 20 minutes.⁸⁴ Against the body louse, BHC dust was more effective than either DDT or DDD.⁶⁷ In other tests with the body louse, 50 per cent were killed with 0.016 mg. of the gamma isomer per gm. of insect body weight as against equivalent kills with 0.30 mg. of p; p'-DDT per gm. of insect body weight.⁸⁴

A 1 per cent solution of 10 per cent gamma BHC in fuel oil, sprayed on open fields showed good control of the American dog tick.⁹⁵ Against the lone-star tick, *Amblyomma americanum*, effective control has been obtained with a 5 per cent dust rubbed into the hair of dogs. The action was slow, 12 to 14

hours being required to kill; feeding was stopped within 2 hours.⁹⁶ Dipping cattle in a 0.5 per cent solution of 50 per cent wettable BHC (10 to 13 per cent gamma isomer) gave protection against this parasite for 7 to 10 days.⁹⁷ In oil base preparations and water suspensions, BHC at 0.005 per cent gamma isomer killed adult females of an arsenic-resistant tick, *Boophilus discoloratus*.⁹⁸

Fleas, *Ctenocephalides canis*, were controlled in 4 hours' time with a 5 per cent BHC dust rubbed into the hair of dogs. Little or no residual action was indicated, however, as reinfestation occurred in 3 to 4 days even though an odor of BHC remained.⁹⁹

Against the bedbug, BHC has shown a high degree of toxicity⁸¹ and has given more effective control than several other insecticides tried, including DDD and DDT.⁶⁷

Roaches (*Periplaneta americana*, *Blatta germanica* and *Supella supellec-tilium*) were controlled in 5 room houses by 250 ml. of BHC dust containing 10 per cent of the gamma isomer. They were affected in 1 hour and killed in 12 hours, but residual effectiveness was limited; the eggs of the roaches were not injured.⁹⁹ Crude dusts containing 0.5 and 1.0 per cent BHC have killed high proportions of roaches, *P. americana*, with the 1.0 per cent dust driving the roaches out of cracks.⁸⁴

Snails of the genera *Planorbis* and *Bulinus*, intermediate hosts of *Schistosoma*, were controlled in laboratory and field tests within 24 hours by dust containing 5-6 p.p.m. of gamma BHC.^{100 *}

CHLORINATED CAMPHENE †

Chlorinated camphene, with the approximate empirical formula $C_{10}H_{10}Cl_2$, contains 67-69 per cent chlorine.^{101, 102}

* The authors have not confused snails with slugs—but believe that this remarkable observation should be brought to the attention of public health personnel.

† Most commonly known by its trade name Terphene, also in the literature as 2255 or Hexalene 347.

Stearns, Parker, LeRoy, and Lynch first called attention to its insecticidal properties in 1946.¹⁰³ The solid form may be stored safely in most containers; concentrated solutions not entirely free from moisture require containers of specific materials.¹⁰²

In space-spray tests (Peet-Grady) comparing chlorinated camphene and aerosol grade DDT with the Official Test Insecticide (pyrethrum base), both chemicals were superior to the O.T.I. against the house fly. Further tests with varying dosages and concentrations showed DDT to be better than chlorinated camphene at concentrations of less than 0.1 per cent and volumes less than 0.3 ml., but at higher concentrations and volumes, their effectiveness was equal. Since chlorinated camphene does not produce rapid knock down,¹⁰³ the inclusion of 1 to 2 per cent of a paralytic agent is advisable in space spray formulations.

As a residual toxicant, this product is reported to compare favorably with DDT; however, the tests were made under conditions of long exposure, and the number of minutes required for complete paralysis was considerably greater for chlorinated camphene. In 60-minute exposure periods, residues of 200 mg. per sq. ft. of this compound were less effective than equal deposits of DDT.⁶⁵ This relation was confirmed under field conditions.⁶⁶

In tests against *A. quadrimaculatus*, 60-minute exposures of the adult insects to deposits of 200 mg. per sq. ft. of both DDT and chlorinated camphene gave comparable results for 8 weeks after spray application; beyond this interval, chlorinated camphene lost residual toxicity more rapidly than DDT.⁶⁵

Used against fourth-instar larvae of *A. quadrimaculatus*,⁸⁹ chlorinated camphene gave nearly complete control at 0.01 p.p.m. in 48 hours, and at this concentration was comparable to DDT but slower in action; at lower concentra-

tions, it was not equivalent to DDT. In laboratory and field tests with *Aedes sollicitans*,¹⁰³ chlorinated camphene compared favorably with DDT when applied at the rates of 0.2, 0.4 and 1.0 lbs. per acre.

As a fly larvicide, 1 per cent chlorinated camphene emulsions applied to manure at 100 to 200 mg. per sq. ft. were less effective than chlordane and benzene hexachloride but more effective than DDT. At 400 mg. per sq. ft., chlorinated camphene was not quite equal to chlordane and benzene hexachloride.⁷⁴ Using nymphs and adults of the bedbug as test insects with a direct spray method, 5.8 per cent chlorinated camphene was nearly comparable to DDT. As a residual toxicant, it was as effective as DDT against bedbug adults but somewhat slower in its action.¹⁰⁴

The product was superior to DDT in the control of German roaches with 2.5 per cent kerosene sprays or less, and equal to DDT at 5.0 per cent strength.¹⁰⁴

PIPERINE COMPOUNDS * AND PYRETHRUM

A synergist combined with an insecticide not only increases the initial effects of the insecticide by providing quicker knock down and greater kill, but often extends the duration of its residual effect. In this way, newer synergists have increased the effectiveness of pyrethrum in public health work. One of these is piperonyl cyclonene (cyclohexenone) which, because of its safety and efficiency in activating small amounts of pyrethrum, led to the study of related compounds.

Piperonyl cyclonene with pyrethrins has been used indoors with success in aerosols and household sprays in control-

* Piperonyl cyclohexanone (now piperonyl cyclonene)¹⁰⁵ and piperonyl butoxide are trade names accepted by the Insecticide Division of the Production and Marketing Administration, U. S. Department of Agriculture, for labeling purposes. They are generally used by the trade and in laboratories; they have no official endorsement.

ling mosquitoes, house flies, fleas, ants, gnats, and sandflies.¹⁰⁶ In laboratory tests, residual deposits of 10 mg. pyrethrins and 200 mg. piperonyl cyclonene per sq. ft. killed more than 75 per cent adult female *A. quadrimaculatus* mosquitoes during the first 23 weeks after applications. At similar concentrations, very little residual effectiveness was shown against female house flies but more effective results might be obtained at higher concentrations.⁶⁵ Success has been reported with dust combinations against roaches, body lice, and household ants.¹⁰⁶ The dust combinations show promise of value in murine typhus control for the reduction of rat ectoparasites but seem to lack the desired residual toxicity for this purpose, especially against rat fleas.

In comparison, combinations of piperonyl butoxide, a related synergist, and pyrethrum are especially effective against house flies but less so against mosquitoes. These combinations are likewise stable and safe to use. Dusts and wettable powders with piperonyl butoxide and pyrethrum have been reported as giving very satisfactory control of roaches, being effective for 60 days or longer.^{105, 106}

EFFECTS OF CERTAIN NEW INSECTICIDES ON WILDLIFE

As long as insecticides are used only in domestic surroundings, there is no danger of creating undesirable biologic imbalances. However, when these chemicals are applied over extensive, unoccupied areas, e.g., as ground- or aerially-dispersed fogs, mists, or dusts, to kill aquatic or terrestrial insects of importance to health, forest conservation, or agriculture, serious consideration must be given to the hazard they may present to wildlife species related to the economy and happiness of man. The peril to these forms may be obvious, direct, and immediate, or it may be insidious, indirect, and delayed. The measurement of

its final consequences is a time-consuming, expensive and highly specialized undertaking. The widespread area-application of insecticides and acaricides for public health purposes can be justified only by rational determination that the health values involved transcend those of all other factors contributing to man's welfare, including the preservation of useful wildlife. This was recognized in a joint statement of policy regarding the use of DDT in this country by the U. S. Army and the U. S. Public Health Service.¹⁰⁷

Preliminary and later trials with DDT for the control of mosquitoes and forest and agricultural pests demonstrated that it was severely damaging to a wide variety of animal life. Cold-blooded forms such as fish, crabs, crayfish, frogs, turtles, and snakes were relatively more sensitive to its effects¹⁰⁸⁻¹¹² than were birds and small mammals.¹¹³⁻¹¹⁶

In view of the early findings, a series of investigations was undertaken by several governmental research agencies at various locations throughout the country to determine the overall effects of the use of DDT and to ascertain at what dosage, if any, and in what manner and physical state, it could be used routinely without being significantly harmful to organisms of economic or recreational importance. The U. S. Fish and Wildlife Service and the Bureau of Entomology and Plant Quarantine assayed the effects of single treatments using relatively large doses. In reviewing these studies, some of which were made coöperatively, Cottam and Higgins¹¹¹ concluded that single treatments for the control of forest insects at the rate of 1 lb. per acre were not detrimental to terrestrial wildlife but that dosages of 5 lbs. per acre were dangerous. These findings may be of importance if area-wide applications are made for the reduction of arthropods of public health importance.

The U. S. Public Health Service, work-

ing in coöperation with the U. S. Fish and Wildlife Service, has confined most of its investigations to the influence of smaller applications repeated routinely. Tarzwell^{63, 117} found that, while fish could withstand relatively large single doses, they were affected adversely by repeated applications of small quantities down to certain levels. Airplane sprays and aerosols at discharge rates of 0.1 lb. of DDT per acre applied over ponds each week for 2 seasons caused no significant change in plankton¹¹⁸ or fish populations.¹¹⁷ Similar results were reported by Hess¹¹⁹ following a season's treatment of one of the Tennessee Valley Authority's reservoirs. During a single summer, this rate of application over the watered portion of a wildlife refuge in southeastern United States had no apparent effect on bird or mammal populations in adjoining areas.¹²⁰ Ground applications of DDT to watered areas of 0.05 lb. per acre repeated each week¹¹⁷ were effectively larvicidal against mosquitoes and not dangerous to fish. Dusts were less toxic than oil solutions, but DDT emulsions, which kill fish at concentrations of more than 0.1 p.p.m.,^{109, 110, 117} were found to be so dangerous that their use was not recommended.

Limited studies with other insecticides have shown some to be less toxic and others more toxic than DDT. Chlorinated camphene⁶³ is very poisonous to fish and thus is unsatisfactory as a larvicide. DDD was less toxic to fish than DDT; however, routine treatments at 0.1 lb. per acre killed fish. Chlordane was nearly as toxic as DDT and should be used at dosages less than 0.1 lb. per acre.

TOXICITY OF INSECTICIDES

With the exception of DDT, most of the insecticides discussed in this paper are so new that their limitations and their full scope of usefulness in public health practice have not yet been thoroughly investigated. There has been even less time for studying their toxicity to mammals, including man. Until comprehensive information on this subject is available, it is desirable to review data not only from public health literature but from that of agriculture and other biological sciences. This is necessary both for present safety and for the final evaluation of insecticides, which must be chosen as much for their harmlessness to man and domestic animals as for their destructive effects on insects threatening human health.

TABLE 2

Lethal Doses of the Newer Insecticides Reported by Various Authors

| Compound | Animal | Route | Formulation | L.D.O. | L.D. 50 | L.D. 100 | Authority |
|--------------------------------|---------------|-------|-------------|--------|--------------|------------|-----------------------------------|
| DDT | rats | P.O. | corn oil | 70 | 115 | 230 | Parker and Beacher ¹⁰⁴ |
| DDD | rats | P.O. | | | 2,500 | | Lehman ¹²¹ |
| Chlordane | mice | I.V. | emulsion | 30 | approx. 50 | 70 | Food & Drug ¹²² |
| | rats | P.O. | | | 225-250 | | Ingle ¹²³ |
| Benzene hexachloride 12% gamma | mice | P.O. | | | 600 | | Furman ¹²⁴ |
| Piperonyl butoxide | rabbits | P.O. | | | 5,300 | | Dove ¹⁰⁶ |
| | dogs and rats | P.O. | | | 7,950-10,600 | | |
| Chlorinated camphene | white rats | P.O. | kerosene | 160 | 280 | 400 | Parker and Beacher ¹⁰⁴ |
| | white rats | P.O. | corn oil | 73 | 120 | 145 | |
| | dogs | P.O. | | | | 25 or less | Food & Drug ¹²⁵ |

L.D.O. equals largest dose which killed none of ten or more animals. L.D. 50 equals smallest doses which killed half of ten or more animals. L.D. 100 equals smallest dose which killed all of ten or more animals. All doses are in terms of milligrams per kilogram of body weight. P.O. = Peroral; I.V. = intravenous.

It is often observed that the lethal dose of each of the newer insecticides, including DDT, varies widely for different and even for the same species of animal and by the same method of application, except intravenous administrations which show sharp dosage-mortality relationships. This suggests irregular absorption and perhaps variation in the reserve detoxifying power of the liver or other tissues as an explanation for the experimental results. However, the importance of species differences should not be underestimated. In practice, one cannot study the toxicity of an insecticide for rats and, with certainty, predict its safety for man. Furthermore, one solvent or formulation may greatly enhance the absorption and, therefore, the effective toxicity of an insecticide. Thus the same concentration of an insecticide may be absorbed more extensively when prepared in vegetable oil than in other organic solvents which are inherently more toxic. Some of these facts are illustrated in Table 2, which shows the acute lethal doses of the various insecticides discussed in this article.

Table 3, modified from Lehman,¹²¹

TABLE 3

*A Comparison of the Acute Oral Toxicity for Rats of the Newer Insecticides with DDT*¹²¹

| Insecticide | L.D. 50 mg./kg. | Ratio to DDT |
|------------------------------------|--------------------|-----------------|
| Beta Isomer, Benzene Hexachloride | 6,000 | 1/24 |
| DDD | 25,000 | 1/10 |
| Delta Isomer, Benzene Hexachloride | 1,000 | 1/4 |
| Alpha Isomer, Benzene Hexachloride | 500 | 1/2 |
| Chlordane | 500 | 1/2 |
| DDT | 250 | 1 |
| Gamma Isomer, Benzene Hexachloride | 125 | 2 |

compares the acute toxicity of the various insecticides with that of DDT. There is considerable parallelism between the toxicity of the various compounds to insects and to warm-blooded animals. Thus, the least toxic compound may not be the safest since it may have to be used in higher concentration to obtain effective insecticidal action. In any event, since acute toxicity bears no relation to chronic toxicity, the acute

toxicity is chiefly of value in judging the safety of a substance only for a short time after exposure.¹²¹ It is emphasized that the chronic toxicity to man of most of the insecticides discussed in this paper is entirely unexplored.

DDT—This compound has been studied extensively from the standpoint of its toxicity, yet much remains to be learned. An excellent summary of present information based on much original work with 107 references to the literature has been made by Stammers and Whitfield.¹²² They conclude that "... DDT when used as an insecticide, with reasonable intelligence and the precautions normal to the use of modern insecticides, is harmless to man and animals. It is, nevertheless, possible by misuse in its application, to incur risk to man and animals. The possibilities of cumulative effects from storage of DDT in milk and tissues of sheep and cattle require further investigation."

An interesting report of acute DDT poisoning in 28 men following the ingestion of a 10 per cent DDT, 90 per cent wheat flour mixture has been given by Garret.¹²³ The exact amount consumed was not known but some of the men must have taken several grams of DDT. Vomiting, numbness, and partial paralysis of the extremities, mild convulsions, loss of proprioception and vibratory sensation in the extremities, and hyperactive knee-jerk reflexes were the immediate toxic effects. The symptoms were transient except in the three men who had taken the largest portions.

There have been reports of several deaths alleged or intimated to be due to the ingestion or inhalation of DDT.^{122, 124-126} In view of its demonstrated accomplishments in the fields of applied public health and agricultural entomology on the one hand, and, on the other, the presence of this insecticide in millions of homes and the frequent and prolonged exposure of the many individuals employed in its ap-

plication, it is of paramount importance to ascertain correctly the actual hazard to human life of DDT under normal circumstances. Thus far,^{122, 127, 128} the evidence against the compound as a cause of death when used prescriptively is negligible, though instances of accidental deaths due to DDT or its accompanying diluents, adjuvants, etc., or to both, have undoubtedly occurred.

Perhaps the most complete account of a fatal poisoning involving a DDT formulation is that¹²¹ of a 58 year old man who drank 120 ml. of a commercial preparation containing DDT, 5 per cent; "Lethane" (384 special), 2 per cent; xylene, 7 per cent; and deodorized kerosene, 86 per cent, following it with a quart of milk and several glasses of beer. The symptoms consisted of the rapid onset of epigastric pain and the vomiting of bloody material. These continued with varying intensity until death in coma on the 7th day. No urine was passed from 2 hours after ingesting the DDT until the 6th day, when the patient was catheterized. Thirty-six hours after poisoning, spastic contractions of the fingers and wrists began. The NPN on the 6th day was 150 mg. per cent. Examination on that day revealed an enlarged tender liver, unequal non-reacting pupils, and no tremor or pathologic reflexes. Autopsy findings included gastric hemorrhage, centrolobular necrosis with fatty degeneration of the remaining liver parenchyma, and tubular degeneration of the kidneys. This careful study emphasizes the danger of acute oral poisoning with insecticides. However, in view of the author's demonstration that kerosene by mouth produced in rabbits the same and only slightly less severe damage than corresponding amounts of the commercial insecticide or of 5 per cent DDT in kerosene, many readers will conclude that the diluent of the insecticides as well as the DDT contributed to the fatal outcome of this accident and that the clinical

and pathologic findings were probably a composite picture of the effects of DDT and of kerosene.

Another well studied but even less convincing report¹²⁶ of a death believed to be due to DDT concerns a 47 year old man who had been working in a room sprayed with 6 per cent DDT in kerosene. Symptoms (pruritic eruption on trunk and extremities) occurred 24 hours thereafter but death did not supervene until the 57th day* after exposure! Lesions simulating periarteritis nodosa were noted at biopsy and autopsy, as a consequence of which, the authors advance the suggestion that DDT may be an allergen capable of inducing hypersensitivity. In view of the minute amount of DDT consumed, the relatively long interval between exposure and death, the initiation prior to exposure of some of the symptoms mentioned, the failure of other investigators to demonstrate experimentally allergic properties of DDT,¹²⁷ and the paucity of pronounced clinical or pathologic manifestations of the type commonly associated with DDT poisoning, the authors' conclusions are untenable until validated by confirmatory evidence. Pending that time, this paper is representative of a type which may occasion much harm by providing an ostensible basis for compensation claims or by interfering with the fullest utilization of a powerful agent for improving health, comfort, and economy.

DDD—This analog of DDT has been reported¹²¹ to have a toxicity for rats (Table 2) about one-tenth that of DDT.

The pathology of chronic DDD poisoning in dogs consists of adrenal cortical atrophy and a high-grade liver damage including, chiefly, fatty degeneration and, to a lesser extent,

* The authors' summary states that "death occurred 25 days following exposure to DDT . . ." Nevertheless, the date of exposure was given earlier in the article as November 10; that of expiration, January 6.

atrophy, necrosis, and cirrhosis.^{129, 130}

Benzene hexachloride—The commercial product (approximately 12 per cent gamma isomer) has been considered of rather low toxicity¹³¹ whether given by mouth or applied to the skin of cattle and mice in excess of what would be used in agricultural practice. There is some evidence that the gamma isomer is a central nervous system stimulant while the alpha isomer is a depressant. Bushland, Radeleff, and Smith¹³² found no ill effects to domestic animals from benzene hexachloride (10 per cent gamma isomer) when used every 4 days as a dip in 1.5 per cent concentration. However, 3 out of 3 cows were killed when a preparation containing 50 per cent gamma isomer was used at the same concentration and 1 out of 3 when the concentration was 0.75 per cent.

Dogs fed 10 mg. per kg. of gamma isomer daily show mild changes in the liver, bone marrow, lymphoid tissues, adrenal cortex, and cerebrum. Anatomically the lesions do not seem to account for death, and the possibility that the true cause is vascular collapse or sensitization must be considered.¹³⁴

Dogs fed 60 mg. per kg. of alpha isomer daily show at death great emaciation, atrophy of various tissues, marked liver damage, moderate kidney damage, and lesser injury to other viscera. The alpha isomer is stored largely in the fat, liver, and adrenals.¹³⁴

Although in single oral doses, the toxicity of the isomers of benzene hexachloride decreases in the order: gamma, alpha, delta, and beta, it has been observed in chronic toxicity experiments that the beta isomer is most toxic. The contrast is probably due to the fact that some isomers, not so readily destroyed by the tissues, are stored chiefly in tissues of high steroid content. After 12 weeks on 500 p.p.m. diets, female white rats showed the following concentrations in the fat (mg. isomer per gm. of fat): beta, 7.5; alpha, 2.4; delta, 0.5;

and gamma, 0.4. There is evidence to show that the gamma isomer is destroyed in the liver and that the liver hypertrophies and presumably becomes more efficient in the task.¹²⁹

Chlordane—This compound was shown to have marked toxicity for sheep and goats.¹³⁰⁻¹³² Chlordane wettable powder and emulsion formulations with 1.5 per cent active ingredients were used as dips at 4 day intervals, a dosage level higher than would be used in actual practice; 8 dips were given to surviving animals. Two or more of each group of 5 goats or sheep died after 3 or more dips. The principal clinical manifestations of chlordane poisoning were neurological—optic nerve or optic center impairment, ataxia, convulsions, and collapse. Animals killed by chlordane showed congestion of the brain and spinal cord, subserosal petechial hemorrhages most frequent on the antemesenteric border of the small intestine, peripheral and midzonal necrosis of the liver, and occasional variable lesions of the kidneys, stomach, and heart.

Ingle¹³³ found the acute and chronic toxicity of chlordane essentially the same as that of DDT for rats. The time lag between the administration of an acute lethal dose and death averaged 1 day for DDT and 4 days for chlordane. He also noted greater liver damage with DDT, greater pulmonary damage with chlordane.

Chlorinated camphene—This chemical was found to be slightly more toxic to white rats than was DDT when either was administered in corn oil.¹⁰⁴

Solutions of chlorinated camphene are absorbed readily through the skin and persons handling such solutions require adequate protection.¹³⁴

Piperine compounds—Dove¹⁰⁶ has given evidence establishing the remarkably low toxicity of piperonyl butoxide (see Table 2) which is recommended for use in the field, household, and food processing plants.

Public Health Service at Savannah, Ga., in the preparation and critical review of this article: Mr. Walter C. Baker, Dr. Richard W. Fay, Miss Mary Goette, Dr. Wayland J. Hayes, Jr., Mr. Jens Jensen, Mr. Willis Mathis, Dr. Robert H. McCauley, Dr. H. P. Nicholson, Mr. Kenneth Quarterman, Mr. H. Stierli, Dr. Clarence Tarzwell, and Dr. William M. Upholt.

Field Training Fellowships for Public Health Engineers

The Michigan Department of Health is again offering summer field training opportunities to persons desiring experience in public health engineering work. The training period is three months, during which time the students will be assigned to county health departments as assistants to the staff public health engineers.

Applications will be accepted from graduates or undergraduates of recognized professional schools with training in public health or sanitary engineering, dairy science, food technology, bacteriology, etc. Undergraduates must have

completed their junior year of study. Stipends to assist with living expenses are paid by the W. K. Kellogg Foundation; the amount is approximately \$150 per month. The program is approved by the Veterans Administration and veterans are eligible for the maximum subsistence allowance in addition to the stipend. Ownership of a car is desirable and car owners will receive an allowance for driving their automobiles.

For information write to Mr. John M. Hepler, Director, Bureau of Engineering, Michigan Department of Health, Lansing 4, Mich.

Is the Rh Factor a Public Health Laboratory Function?*

ANNA I. VAN SAUN, F.A.P.H.A.

Director, Division of Laboratories, Board of Health, Paterson, N. J.

WHEN the discovery of the Rh factor was announced by Landsteiner and Wiener¹ in 1940, preceded by the clinical observations of Levine and Stetson² in 1939, it is probable that none of these people thought that Rh factor determinations would ever be made in a public health laboratory. The hospital and research laboratory seemed the logical place for such work. The inability of most hospitals to handle this problem at that time, together with a lack of understanding of the value of the Rh factor by some pathologists, pointed to the need of a central laboratory for this work.

In 1944³ Dr. Theodore Graham, Chairman of the Maternal Welfare Committee of the Passaic County Medical Society, believing that one of the functions of a Board of Health is to keep down the infant and maternal death rate, proposed to Dr. Frederick P. Lee, the Health Officer, that we take up Rh determinations in our laboratories with a view to establishing an Rh-negative blood donors club. He pointed out that since ours is the only public health laboratory in Passaic County (serving communities totalling 250,000 people) we receive most of the blood specimens sent by physicians in conformity with the state law requiring a blood test for syphilis on all antepartum women.

We agreed to take over the work which was to include Rh factor determinations on specimens from the blood bank

of one of our largest hospitals. This latter work would be terminated when the hospital could handle it and was terminated in 1945.

Blood grouping has been added to our work since marital incompatability of the blood groups is sometimes responsible for accidents of pregnancy and childbirth.

For the past three years we have received a total of 21,000 specimens of blood from antepartum women. We thus became, as far as we know, the first public health laboratory in the country to perform Rh tests.⁴

Our most pressing problem was securing immune serum for our work. In 1944 there was very little on the market, but we managed to obtain enough for our first tests from three different sources together with some given us by friends and a small quantity from two of our own patients. We have had but two patients whose blood possessed a high enough titer to warrant its use for anti-Rh serum and these patients were not coöperative.

Since serum continued to be scarce we decided to try comparative tests with human and animal sera, using the human serum slide test of Diamond, a test which had already been used by Tisdall⁵ for large numbers of specimens and an animal serum slide test with which a good deal of experimental work had been done.* We obtained human slide

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

* A necessity for the slide test is a good viewing apparatus having gentle heat. One may now be obtained together with indelibly marked slides, from a firm which distributes typing serum.

testing sera from three different sources. These sera checked with the human serum tube test and possessed the advantage of being cheaper than the tube test or animal anti-Rh serum. We found that in our hands the animal serum tended to give occasional false positives. Such a case was recently noted by Pettit and Evans in a Pasadena hospital laboratory.⁶

At first most of the Rh typing serum was secured from sensitized mothers of erythroblastotic infants, but in 1945 Hill, et al.⁷ prepared a serum by injecting Rh positive blood into previously immunized individuals. This serum he lyophilized. It has given excellent results in this laboratory but should be tested with known Rh sub-types before use.

Wiener⁸ has recently announced that he has prepared an immune serum by immunizing normal male donors.

Comparative tests with 250 lots of human tube testing sera have taught us that no serum is perfect though the serologists responsible for the preparation of such sera do their best to make them so.

We have found that if a tube test serum begins to deteriorate it may be noted quickly by the use of a good method of reading and by testing it with a relatively large number of specimens. We follow a method suggested by Wiener⁸ which makes use, not only of a macroscopic reading but also of a direct tube reading under the microscope.

We follow implicitly the method put out by the purveyor of a testing serum. We do not retitrate the serum nor do we dilute further what seems to be a strong serum.

Anti-Rh serum should not be purchased too far in advance and, of course, contaminated serum should never be used. We never use hemolyzed patients' blood for any sort of serological work.

In our opinion no one serum is safe to use without being checked by other

sera. We are well aware of the fact that the busy hospital laboratory, probably understaffed and limited for time and money, will use one serum. What that serum is to be will depend upon the person in charge, his experience with the Rh factor, and the training of his technicians.

Our experience has shown us that a central laboratory is highly desirable for routine Rh testing of antepartum women. A laboratory which might test a dozen specimens of blood a week would be in no position to judge of the value of a testing serum.

We believe that the National Institute of Health has embarked on an attempt to standardize anti-Rh and blood grouping sera. This is something which is badly needed. We have received various lots of mislabeled anti-Rh sera and sera too weak to be safe to use, as well as some which were apparently incompletely absorbed.

Since we are in close touch with our obstetricians it has seemed advisable to test, not only for positivity and negativity, but also to sub-type all Rh negative women, their husbands, and children.

Agglutinins and blocking bodies are determined on all Rh-negative women. At first we used the original technique suggested by Wiener,⁹ but at present we use modifications suggested by Diamond, et al.^{10, 11}

All women developing these reactions are retested throughout their pregnancies at the discretion of their physicians. All such reactions, if positive, are reported by telephone and all reports are made to the physician only.

Any woman who gives a history of abortions or other accidents of pregnancy, even though she tests positive with the 85 per cent serum, is sub-typed. Only two such women have been found to be in the Rh-negative class though this particular sub-typing has only been carried on in 1947. Neither of these

* Occasionally a physician will send in both the wife and husband together before the Rh factor has been determined.

women had agglutinins or blocking bodies.

Out of 1,036 men sub-typed who were positive with the 85 per cent serum, 30 proved to be in the Rh-negative class.

Although this paper is not written from the clinical standpoint we feel that perhaps a few details concerning the number of erythroblastotic and stillborn infants we have had on our records might be of interest to public health laboratories engaging in this work.

A complete card index is kept of our cases and we supply physicians with cards upon which they enter facts regarding the termination of the pregnancy, condition of mother and child, and other facts of interest to us.

We occasionally issue a card to an Rh-negative woman but only with the permission of her physician. Cards are soon to be provided by the Passaic Co. Medical Society for all persons Rh tested in our laboratory.

Women on our records who have had erythroblastotic or stillborn infants are in three classes: those who are Rh-negative and have had no agglutinins or blocking bodies, those who are Rh-negative and have agglutinins or blocking bodies, or both, and those who are Rh-positive.

Of 2,507 Rh-negative women, 46 have borne erythroblastotic infants, the infant mortality with either class being about 50 per cent. Seventeen have had stillborn infants. Nineteen normal infants were born to women having agglutinins and blocking bodies.

There were 6 Rh-positive women who had erythroblastotic infants. Two of these children lived and 4 died. We were not able to explain these anomalies, although they might be due to differences in the blood groups. In one case it was not.

A family was noted, three of whose members possessed the rare Rh' Rh'' factor. Two of these persons are women. One other person, a man, not of this family, also possessed this type.

Apparently the physicians of Passaic County are thoroughly convinced that the Rh factor is indeed a function of this particular public health laboratory. They assure us that the work we have done is very worth while. It is too early to note the effect of this work on the infant and maternal death rate.

The trend seems to be toward an increasing use of public health laboratories for Rh factor tests. Levine¹² has recently suggested the use of the public health laboratory for Rh factor determinations and we understand that several state laboratories are already doing this work.

While our work is based on the public health laboratory approach and does not touch on the transfusion problem which should very properly be left to the hospital laboratory, we are occasionally asked to do an Rh and blood grouping test in an emergency. Many hospitals still do not Rh type patients who are to receive transfusions, and transfusion reactions are still being reported.

The Rh Negative Blood Donors Club has now on its rolls more than 80 active members. All names of Rh-negative persons are sent to the Secretary of the Passaic County Medical Society who in turn contacts these persons, suggesting membership in the club.

Our work has been necessarily limited at times by the shortage of testing serum. We feel that testing for the more unusual types such as Hr, discovered by Levine in 1941,^{13, 14} is best left to the research laboratory.

SUMMARY

The work of three years on the Rh factor in a public health laboratory is described.

A central Rh testing laboratory is suggested for groups of communities.

The use of human anti-Rh testing serum is preferred.

The sub-typing of Rh-negative women, their husbands, and children,

and determinations of Rh antibodies are recommended.

A successful Rh-negative blood donors club is described.

NOTE: Thanks are due to Dr. Alexander Wiener and Dr. Philip Levine for many kindnesses shown us and to Dr. Frederick P. Lee for advice and criticism as well as to Miss Evelyn Brown, Mrs. Agnes Juneiman, Miss Grace Donahue, and Miss Elinor Fairweather who have been responsible for the actual performance of this work.

Blood Grouping and Rh Typing in a State Public Health Laboratory*

ROBERT A. MACCREADY, M.D., AND ROBERT T. MCGEE

*Assistant Director and Junior Bacteriologist, Division of Communicable Diseases,
State Department of Public Health, Boston, Mass.*

IN spite of the safeguard of routine cross-matching, an incorrectly typed blood is sometimes used and can damage or even kill. The free distribution of blood on a state-wide scale, therefore, involves a staggering responsibility. Realizing that blood released from the state blood bank *must* be correctly labeled, the Massachusetts program from the start has included the blood grouping and Rh typing of every unit of blood by two completely independent but co-operating laboratory units within the department. From our experience the wisdom of this course has become perfectly obvious. If there is any disagreement whatsoever in the typing of a blood it is used for fractionation products only. It is never released as whole blood, even though the discrepancy is completely liquidated upon repeat checking by the two laboratory units.

The entrance of the Massachusetts Department of Public Health Diagnostic Laboratory into a state blood typing program a year ago arose, in fact, in response to the needs of the Massachusetts blood program whose mobile units are now collecting about a thousand bloods a week—a participation in a new public health field recently well discussed by Janeway.¹ Meanwhile the Massachusetts Legislature had passed an act expanding the department's laboratory approval program to include blood

grouping, Rh testing, and cross-matching, and the Diagnostic Laboratory's activities were increased accordingly to include evaluation of some 63 hospital and private laboratories within the state desiring approval for these tests. As soon as possible blood grouping and Rh typing of prenatal bloods, as requested by physicians, were added to further augment the services of the Blood Grouping Section of the State Diagnostic Laboratory. These three activities—check typing for the state mobile blood collecting units, evaluation of laboratories performing blood typing tests, and blood grouping and Rh typing of prenatal bloods—compose our state public health laboratory services in the blood typing field, and will be discussed in order in this paper. We hope later to include some research which is certainly indicated in a venture of this scope. An overall statistical summary of the Rh typings is shown in Table 1.

TABLE 1

Statistical Summary of Rh Typing During First Ten Months at Diagnostic Laboratory

| Typings | Number * | Per Cent |
|----------|----------|----------|
| Rh+ | 16,165 | 83.1 |
| Rh— | 3,131 | 16.1 |
| Rare Rh+ | 146 | 0.8 |
| | 19,442 | 100.0 |

* Includes repeat typings on a number of individuals who returned for second and later donations. Unexplained discrepancies are excluded from this tabulation.

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

Dr. Louis K. Diamond has been our consultant from the beginning, and we are indebted to him for invaluable help

in the organization of this blood typing program, as well as to our own staff and the cooperating members of the Biologic Laboratories. We are grateful also to the Blood Grouping Laboratory of Boston for very generous financial assistance which has been granted to us during this formative period.

BLOOD GROUPING AND RH TYPING FOR
THE MASSACHUSETTS BLOOD DISTRIBUTION PROGRAM

The two mobile bank units collect blood 5 days each week from the various communities throughout the state, roughly some thousand bloods a week. Whether this blood is ultimately distributed as whole blood or processed into fractions for distribution, it is typed both in the field and again at the central Diagnostic Laboratory. Different methods and sera are used in the two laboratories.

The blood group of each donor is determined in the field by the slide test on finger blood, using either human blood grouping sera obtained from the Blood Grouping Laboratory at the Children's Hospital in Boston, or human blood grouping globulins manufactured by the department's Biologic Laboratories after the method described by Melin.² At the same time, and on the same slide, the Rh factor is determined by the slide testing method of Diamond and Abelson³—originally proposed by them for detection of Rh antibodies—using 85 per cent (anti-Rh₀ or anti-D) hyper-immune serum from the Blood Grouping Laboratory at the Children's Hospital in Boston. The reading is facilitated by the use of a portable slide viewing box, as described in Diamond and Abelson's original article. Because donor lines must move fairly rapidly in a successful bleeding clinic (slow lines discourage donor attendance), only 85 per cent (anti-Rh₀ or anti-D) typing serum is used at this time. At the Diagnostic Laboratory,

however, both 85 per cent (anti-Rh₀ or anti-D) serum and 87 per cent (anti-Rh₀' or anti-C+D) serum are employed. The blood group and Rh factor are recorded by the field technician on a master working sheet, the results of which are not released until the blood is subsequently checked by the Diagnostic Laboratory.

The check typing by the Diagnostic Laboratory of the department is performed upon the pilot tube of clotted blood, which is collected from the donor at the time of the bleeding. Another pilot tube contains blood in acid-citrate-glucose solution, and is permanently attached to the unit of donor blood for cross-matching tests by the hospital at the time of transfusion.

Serum from the pilot tube of clotted blood is withdrawn for serological tests for syphilis by the Wassermann Laboratory, and cells are withdrawn by the Diagnostic Laboratory's Blood Grouping Section for the check blood grouping and Rh typing tests. To avoid any possible error in blood identity, the Wassermann Laboratory withdraws the serum itself from the pilot tube, and the Blood Grouping Section likewise withdraws the cells which it needs. The remaining clotted blood is left in the original pilot tube for possible recheck until all testing and retesting of the day's run is completed. We feel that these precautions are very important to eliminate divided responsibility regarding the identity of any blood, serum, or cells under testing, because the danger of confusing specimens handled by several workers can become very real indeed!

At the Diagnostic Laboratory the test tube method for blood grouping and Rh typing is used with early-immune anti-Rh serum in contrast to the slide method with hyper-immune anti-Rh serum, which is used in the field. A check typing by a different method and serum is a more substantial check than if the same method and serum were used.

Suspensions of approximately 3 per cent cells in saline are made by transferring cells from the pilot tube of clotted blood by means of applicator sticks. With a little practice the proper strength of the suspension can be judged accurately enough by its color alone. Like the field, the Diagnostic Laboratory uses blood grouping sera from the Blood Grouping Laboratory, or blood grouping globulins from our own Biologic Laboratories. Anti-Rh sera, however, are all obtained from the Blood Grouping Laboratory. The Rh factor is routinely tested with 85 per cent (anti-Rh₀ or anti-D) serum, but, unlike the field, all negatives are retested in addition with 87 per cent (anti-Rh₀' or anti-C+D) serum.

The usual tube technique for blood grouping and for Rh typing is followed.⁴ We have found a wooden rack convenient for holding the tubes in our routine tests. The typing sera are dropped into the tubes *before* the cell suspensions are added so that each tube can be checked to make certain the serum has actually been placed in every tube. The blood grouping preparations are allowed to remain at room temperature, while the Rh preparations are incubated for one hour in a water bath at 37° C. All tubes, both for blood grouping and Rh typing, are centrifuged at low speed for one minute before each and every reading. (Because anti-A and anti-B agglutinations are more easily read after centrifugation, and an occasional weak agglutination will be missed without it, we spin at low speed all the blood grouping tests as well as the Rh typing preparations.) By having an extra set of centrifuge carriers, loading and unloading of a set of tubes in the carriers can conveniently be performed during the otherwise wasted minute while a second set is spinning in the centrifuge. All tubes are read macroscopically by at least two independent workers, and all macroscopic negatives

re-read microscopically. When completed, the results of the run are compared with the results of the field typing. If there are any discrepancies, the blood units involved are excluded from distribution as whole blood, and are fractionated instead, even though the discrepancy is liquidated on the repeat tests always performed by the central and field laboratory units. This procedure is followed to save time, and to avoid all possible chances of error.

Bloods which show macroscopic or microscopic agglutination with 85 per cent (anti-Rh₀ or anti-D) serum are labeled as "Rh positive" and so recorded on the card mailed to the donor, and bloods which are negative macroscopically and microscopically with 87 per cent as well as 85 per cent serum are labeled and recorded as "Rh negative." Bloods which are negative with 85 per cent (anti-Rh₀ or anti-D) serum, but positive with 87 per cent (anti-Rh₀' or anti-C+D) serum are labeled as "rare Rh positive sub-group," and the card mailed to the donor is stamped with the following words:

RARE RH+ SUB-GROUP
DONATE TO RH+ ONLY
RECEIVE FROM RH- ONLY

There has been so much confusion even among physicians about the significance of the Rh sub-types that it seemed wise to include the explanatory phrase. Although a blood which is negative with 85 per cent serum and positive with 87 per cent serum is nearly always an Rh' (Cde), we have used the phrase "rare Rh+ sub-group" as academically more accurate, because without 30 per cent (anti-Rh" or anti-E) serum it is impossible to exclude the rare occurrence of an Rh' " (Rh' Rh") blood. Anti-Rh" (anti-E) serum would be difficult to obtain in the amounts necessary for the volume of Rh typing which we are routinely performing. Furthermore, the likelihood of sensitization to the Rh"

(E) factor by transfusion alone is too remote to be of practical consideration in routine blood typing, since the incidence of the Rh⁺ sub-type is less than 0.2 per cent and it has been shown to be a very weak antigen.^{5, 6} We therefore do not use 30 per cent (anti-Rh⁺ or anti-E) serum in our large-scale routine blood-typing program. To avoid any secretarial errors in copying, all reports are stamped and checked by the participating laboratory workers themselves.

INVESTIGATION OF DISCREPANCIES

The importance of a thorough study of each disagreement between the field and central laboratory was realized at the outset, and the studies have been almost as enlightening as the discrepancies have been annoying. Of the 16,210 bloods typed by the field unit and central laboratory, there have been 63 disagreements on the blood grouping, and 140 disagreements on the Rh factor.

Where disagreement occurred between the field technician and the Diagnostic Laboratory, a complicated series of recheck typings is performed by the Diagnostic Laboratory. The blood is then resubmitted to the field technician for a second typing. This recheck is entirely independent, since the technician does not then know the findings of the Diagnostic Laboratory, nor can she possibly recall her original report on the blood some days before.

All 50 of the completely studied blood group or ABO discrepancies have been liquidated by agreement of the two laboratory units upon rechecking. In contradistinction to some of the discrepancies in Rh typing, they were all caused by human errors in performance or reading; none was the result of aberrant factors in the blood or typing sera.

Our form provides for a similarly involved series of rechecks by the Diagnostic Laboratory, followed by the field technician's independent recheck. As in the ABO discrepancy studies, the Diag-

nostic Laboratory has rechecked the Rh factor by both the tube and slide methods, and in the slide method has used both its regular lot of serum, and serum of the same lot number used in the field, to learn whether the discrepancy is caused by a difference in the typing sera, or by a human error in performance. It will be noted that disagreement here between field and Diagnostic Laboratory is more apparent than real, for the Diagnostic Laboratory agreed with the field technician when it used the slide test and the same lot of serum. It is essentially a discrepancy between sera rather than between laboratories. Interesting and disturbing variations, which occurred during a period when the "cix" lot of serum was used, are now under investigation by a colleague. Studies so far suggest that they may be explained by this reagent containing also a rare variant of the anti-Rh₀ serum.⁷ If this further study should add new knowledge about immunity to the Rh factor, such knowledge has been made possible only by the existence of two independently operating laboratory units where every discrepancy is subjected to thorough investigation.

Unfortunately, since anti-Rh agglutinins are not a normal constituent of human serum, we cannot employ a procedure comparable to the "reverse typing" so useful for checking blood groups, in which the unknown serum is tested against known A and B cells. However, in addition to the regular tests, we recheck all bloods with the albumin technique.⁸ We have lately at times included tube-testing with hyper-immune serum with the cells under test suspended in the donor's own serum, when results have been otherwise equivocal.

One hundred and eleven of the 140 Rh discrepancies were completely studied. Seventy-five were explained by a reversal of the field technician's original findings upon recheck; 13 were liquidated upon reversal of the Diagnostic

Laboratory's first findings; and 23 remain unexplained.

As a direct result of the several disagreements where an Rh-positive slide test was read in the field, but a negative reading was made at the Diagnostic Laboratory—some explained and some unexplained—we now include slide tests on all prenatal bloods which are Rh-negative by the routine tube test at the Diagnostic Laboratory.

Uncomfortable and crowded quarters, and congestion of donors during certain hours of the day are unsatisfactory working conditions, which have been very difficult to avoid in a mobile clinic, which must accept facilities as they find them. In addition, fatigue from constant repetition of a single task, rare clerical errors, and simple technical inadequacy in performing the tests have all contributed to the mistakes in the field. A number of the errors were due to a single inadequately trained laboratory worker, whose technique greatly improved after further tutelage at the central laboratory. The inexperienced may confuse rouleaux formation in the slide test with true agglutination. At times during the warm weather coagulation seemed to take place before anti-A or anti-B agglutination could occur. For this reason heparin is now to be added to the anti-A and anti-B typing sera. It is already used in the anti-Rh slide typing sera, where it successfully combats coagulation.

We are skeptical of laboratories which report no difficulty at all in their Rh typing. Unless their work is checked on a large scale by a second independent laboratory unit, they are not likely to learn of their occasional mistakes. You cannot have discrepancies if you do not have another laboratory with which to be discrepant! We should therefore welcome discussion from representatives of blood typing laboratories, which have conducted large-scale Rh typing programs in parallel with other laboratory

units, especially if the other laboratory unit employs a different method and different serum.

EVALUATION OF LABORATORIES PERFORMING BLOOD GROUPING, RH TESTING, AND CROSS-MATCHING

Strong indication that local hospitals are committing unsuspected errors from time to time, especially in their Rh testing, is shown by their results on our series of unknown bloods which were sent for evaluation of laboratories desiring approval for blood grouping, Rh testing, and cross-matching under the department's laboratory approval program. Samples of bank blood preserved in acid-citrate-glucose solution were sent to 63 laboratories for blood grouping, for Rh testing, and for use in special cross-matching problems. The results of the blood grouping and Rh typing tests are tabulated in Table 2.

TABLE 2

Statistical Summary of Results of Test Specimens Submitted to Laboratories for Evaluation

| | Total Specimens Tested * | Errors in Blood Grouping | Errors in Rh Typing |
|------------|--------------------------------|-----------------------------|------------------------|
| Series I | 777 | 8 | 61 |
| Series II | 502 | 6 | 34 |
| Series III | 211 | 0 | 5 |
| | 1,490 | 14 | 100 |

* Obtained by multiplying the number of bloods tested by each laboratory by the number of participating laboratories.

As would be expected, there were many more errors in Rh typing than in blood grouping. The 100 Rh typing errors out of 1,490 blood specimens are about 7 per cent—an uncomfortably high percentage of inaccuracies. Actually 23 laboratories performed perfect or nearly perfect typing, while 69 of the 100 Rh errors were committed by just 13 laboratories. Some of them were due to inadequate typing serum, including serum of animal origin, but many were due to poor training and inade-

quate supervision of technicians in this important procedure. While Rh typing tests are easy to perform correctly, they are likewise easy to perform incorrectly. A number of laboratory workers have assumed that they must be doing the Rh work accurately, because they "get about the right number of positives." Certainly occasional errors will hardly be detected by such casual means, and a laboratory's degree of accuracy can be established only by careful evaluation studies, or by an extended performance in parallel with another laboratory. A strong plea is made for more adequate supervision and appraisal of laboratories performing blood grouping, Rh typing, and cross-matching tests.

BLOOD GROUPING AND RH TYPING OF PRENATAL BLOODS

The typing of prenatal bloods upon request is the third activity which the Blood Grouping Section now performs. Its justification as a public health laboratory procedure stems partly from the lack of convenient typing services in certain more rural communities, and partly from its unreliability in some other communities. But because the law requires a blood specimen for a serological test for syphilis at the first visit of an expectant mother to her physician, and because the specimen which is collected for a serological test may be used also for blood typing tests, the great convenience of the state service to both doctor and patient is perhaps the reason most attractive to the many physicians who have welcomed the service. The discomfort and inconvenience of a second venipuncture is avoided: the physician needs only to fill out the necessary additional forms.

The clotted blood specimens received at the Diagnostic Laboratory containing requests for prenatal tests are treated exactly as already described for the pilot tubes received from the mobile blood units. The Wassermann Laboratory

draws off the serum which it needs for the tests for syphilis, and the Diagnostic Laboratory Blood Grouping Section makes a cell suspension for its tube test from the clotted blood remaining in the specimen tube. Although the physician is primarily interested in the Rh factor rather than the blood group, it is administratively convenient for us to include blood grouping on prenatal bloods exactly as on bank bloods. Bloods which are negative by the 85 per cent (anti-Rh₀ or anti-D) serum are tested with 87 per cent (anti-Rh₀' or anti-C+D) serum, and the Rh report is stamped as POSITIVE, NEGATIVE, or RARE Rh+ SUB-GROUP, as the results of the tests indicate.

For an Rh-negative patient, the following instruction to the physician is stamped on the report:

IMPORTANT—Since patient is Rh-negative, submit husband's blood for Rh testing—use enclosed forms.

For a patient belonging to a rare Rh positive sub-group, this slightly different wording is used:

IMPORTANT—Since patient belongs to rare Rh positive sub-group, submit husband's blood for Rh testing—use enclosed forms.

The forms which are sent to the doctor for use in submitting the husband's blood include the following note:

NOTE: Pregnant patients, whose bloods are Rh negative or belong to a rare Rh positive sub-group, and whose husbands are Rh positive, should have blood sera titrated for antibody content, especially multiparous patients, and patients with a history of previous transfusions, late miscarriages, jaundiced or anemic babies, or other evidence of Rh sensitization. Such titrations of antibody content should be performed at a qualified private laboratory; the Department of Public Health is not prepared to perform such service.

In case of transfusion, patients whose bloods are Rh negative, or belong to a rare Rh positive sub-group, should receive only Rh negative blood.

Much confusion about the Rh factor has arisen apparently in the minds of some physicians as well as the laity, even to the point of belief that any Rh-negative mother cannot or should not become pregnant. At the suggestion of Dr. Diamond we prepared an informative flier entitled "The Rh Factor and Pregnancy," which we enclose whenever a negative or rare Rh-positive subgroup report is sent to the physician. We have seen fit, further, to supply the waiting rooms of the bleeding clinics with this flier, for the wording is not too technical for lay consumption, and reassurance is needed for the mild hysteria which has been aroused among the general public.

Without publicity upon our part beyond the original announcements, the service is growing. The first full month we typed a modest 138 prenatal bloods. A half year later we now handle weekly some three hundred prenatal bloods sent to the laboratory for the Wassermann and blood typing tests, in addition to a thousand-odd bloods received from the mobile bank units. Apparently the great importance and convenience of the service meet a definite need of the physicians of the Commonwealth.

While most of the discrepancies in the typing of the bloods collected by the state blood program were the result of mistakes made in the field, where precision is more difficult, rather than by the Diagnostic Laboratory, we are still a little uneasy that the prenatal bloods done by the Diagnostic Laboratory do not have a second typing by an independent laboratory unit. For this reason, we now include Rh slide tests on all prenatal bloods which give an Rh-negative or rare Rh-positive tube test. Although statistical analysis made possible by our discrepancy studies implies an accuracy of at least 99.8 per cent for the Diagnostic Laboratory, by the operation of an independent second laboratory unit also testing prenatal bloods,

we could be sure of still greater accuracy.

SUMMARY

The Massachusetts Department of Public Health is engaged in a large-scale blood grouping and Rh typing program. This program arose in response to the needs of the state blood bank, which now collects some thousand bloods each week. All donors are typed in the field by the slide method, and a pilot tube of clotted blood is rechecked independently at the Diagnostic Laboratory by the tube method. The occurrence of discrepancies from time to time, especially in Rh typing, is eloquent evidence of the value of this double checking in any blood grouping and Rh typing program, and enlightening information has been gained by complete investigations of all disagreements.

In addition the department evaluates laboratories in the state desiring approval for blood grouping, Rh typing, and cross-matching. The results of unknown bloods sent to participating laboratories in several series reveal an uncomfortably high percentage of errors, particularly in Rh testing. Since errors in typing and cross-matching can cause disasters, the great need for more adequate supervision of laboratories performing blood typing tests is therefore stressed.

The program includes also blood grouping and Rh typing of prenatal bloods, as requested by physicians, and the test is conveniently performed upon the same specimen submitted for the required prenatal test for syphilis. The service is valuable as a state public health activity, and the volume of the work is growing. It is hoped that disastrous results, which have previously occurred when Rh-positive blood has been given to pregnant Rh-negative women, will be prevented by this program, as well as more intelligent management of mother and child made possible.

ADDENDUM

Since the presentation of this paper we have discontinued the use of early-immune serum in the tube test and now employ a modification of the test described by Wiener and Hurst (*Exper. Med. & Surg.*, 5:284, 1947) using testing serum high in blocking antibodies

(hyper-immune serum) with 25 per cent human albumin (20 per cent bovine albumin is equally satisfactory). Early-immune sera are fragile, but hyper-immune sera are more stable, are more easily obtained, and may be used conveniently either in the tube (with albumin) or on the slide.

The Production and Proper Use of Rh Typing Reagents^{*}

LOUIS K. DIAMOND, M.D.

Infants' and Children's Hospitals, Boston; the Department of Pediatrics, Harvard Medical School; and the Blood Grouping Laboratory of Boston, Inc.

A SHORT time after its discovery in 1941, it became evident that the new Rh blood type was of clinical importance in transfusion of the Rh-negative individual—man, woman, or child—and sometimes in the pregnancy of an Rh-negative woman. It therefore became desirable to carry out Rh typing both on the recipient and on the donor of the blood transfusion and on prenatal specimens from obstretical patients. From the onset, there was difficulty in procuring a suitable Rh typing reagent and in obtaining clear-cut agglutination with it. Animal sera were found to give results which were often difficult for the beginner to interpret correctly. Human sera were more satisfactory, but obtaining them depended almost entirely on identifying Rh-negative women sensitized through pregnancy with Rh-positive infants, and such patients are relatively scarce. In addition, it was found that these sera were not always sufficiently high-titered to give clear-cut results. What was even more puzzling, many such women produced sera which failed to agglutinate Rh-positive cells suspended in saline solution. It became necessary, therefore, to investigate the reasons for such difficulties in technique and to learn and describe proper methods of Rh typing using the sera avail-

able at the time and thereafter. It was even more important to produce large amounts of Rh typing reagent, particularly during the war when the armed forces required such serum in performing whole blood transfusion as an emergency as well as a standard therapeutic measure.

In 1943, under a contract from the Office of Scientific Research and Development of the National Research Council, these problems were undertaken by our laboratory, and in the last two years the work has been continued with support in part from the U. S. Public Health Service.

The sensitization of an Rh-negative individual to the Rh factor, either through blood injection or through pregnancy, in the case of the woman who bears Rh-positive children, results in two types of antibody. First, an agglutinin that acts on red blood cells suspended in saline as well as in natural media (plasma and serum). Then with continued pregnancies or sensitization through large transfusions or multiple transfusions, the production of an antibody which fails to act on saline-suspended red cells but agglutinates, with varying speed, Rh-positive cells suspended in plasma, serum, or fractions of these, of which the most satisfactory has been albumin. We have called the first the early-immune antibody, the second the hyper-immune antibody.

The standard techniques can be described under the following terms: (1)

^{*} This study was supported in part by a research grant from the U. S. Public Health Service.

Presented before the Laboratory Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

slide test, using either oxalated blood or finger blood, (2) tube incubation test, (3) capillary tube test (Chown). These are illustrated in Chart 1.

The tube incubation test was the first used and the most successful, according to the original method of Levine and of Landsteiner and Wiener. Using the weak animal sera and the relatively weak human sera available in 1941, this was the necessary technique for such testing, since 37° C. incubation for an hour and then centrifugation was the only certain method of producing agglutination of Rh-positive cells by these somewhat impotent antibodies. In subsequent years, as more and more powerful human sera became available, the length of time of incubation could be shortened, and most recently most sera will produce agglutination within 10 or 15 minutes, even without incubation.

The capillary tube test, as developed by Chown, was most satisfactory in that it permitted incubation for ½ hour or more in a very narrow tube and was

particularly saving of serum. Instead of 20 tests possible from one ml. of serum, the Chown capillary tube method permits about 100. It also is fairly easy to read and does not require equipment of the expensive variety such as water baths or centrifuges.

The slide test method, using either oxalated whole blood or blood taken directly from a finger prick, is done relatively easily and most rapidly if the serum is sufficiently potent and avid to give macroscopic agglutination of Rh-positive blood within 2 to 3 minutes.

The slide test technique has been the most satisfactory in most instances, because of its speed and ease of reading even for the inexperienced technician. In addition, slide testing serum is more abundant and more stable.

Some of the errors that have made Rh typing unreliable are, first, the use of weak sera obtained either from animal or human sources, which fail to produce agglutination of Rh-positive cells even when fresh, without prolonged incuba-

FIGURE 1

Rh SENSITIZATION

Tests for Rh Antigens

tion. Too vigorous shaking of the clumped cells after standing or after centrifugation, with such weak sera, often breaks up the clumps into such small masses that they are not visible macroscopically or may be overlooked even microscopically because of the small agglutinates. It is important, therefore, to have a potent serum and not to shake the tube too vigorously before reading. The next error results from the use of a hyper-immune or "blocking" serum or a serum containing both the hyper-immune and the early immune types, which will fail to give satisfactory agglutination of saline-suspended red cells. In general, it is always safer to use red cells suspended in their own serum or in plasma or, if obtainable, in albumin, and perform these tests with potent serum using either a 2 per cent concentration of cells for test tube tests or a 40–50 per cent suspension of cells for the slide test. In the use of the slide test, it is advisable to have an Rh-negative control specimen since too long a period of observation, particularly with a slow serum, may lead to drying and rouleaux formation that is mistaken for positive agglutination. One should read as positive only the cells that show clear-cut, gross agglutination, within 3 minutes or less, before the slide preparation has begun to dry.

Another important consideration in the proper use of Rh typing reagents is the knowledge that individuals having the rare sub-types Rh' or Rh" (in the English nomenclature, C and E) are just as likely to develop sensitization to the common Rh blood type, Rh₀ (or in the English nomenclature, D), as are Rh-negative persons. For transfusion purposes, therefore, it is important to test the recipients of blood and women undergoing prenatal tests with an anti-Rh₀ or anti-D or so-called "standard" Rh typing reagent. Anyone negative to this reagent is susceptible

of sensitization to this common factor which is present in 85 per cent of the white population.

Although it is difficult to sensitize an Rh₀ individual who lacks the Rh' or Rh" sub-types to these rare types (and statistically the chances of doing so are very small), such a difficulty may become important in the women with obstetrical complications. For this reason it has become the practice in many hospitals and blood banks to use an 87 per cent serum, or if possible all three Rh typing reagents on donors of blood transfusions and on the husbands of Rh-negative women. Since a serum containing the anti-C and anti-D factors (the 87 per cent serum) is much more common and more easily obtainable, whereas the Rh' or E factor is relatively rare (<0.2 per cent), the anti-C and D serum has become the standard for use in blood banks on donors' blood specimens. In an effort to determine the need for such a routine, several thousand cases of Rh sensitization were reviewed. In no case was there any evidence that the injection of a C-positive or E-positive blood sample without the D factor produced sensitization in an Rh-negative individual. On the other hand, any number of cases were encountered in which because an 87 per cent serum had been used and a person identified as Rh-positive when actually she (in most cases this occurred in women patients) was negative to the D factor—the most common and most important of these—Rh sensitization occurred because such a D-negative person was then given Rh-positive blood containing the D factor. It therefore seems, from a practical standpoint, that it would be much wiser to use only an 85 per cent anti-D serum in all obstetrical clinics and possibly in all blood banks. This does not mean that the more inclusive sera, and in fact several different sera, having specificities anti-C, anti-D, anti-E, and anti-c and others if available,

should not be stored and used on special investigative problems in a laboratory equipped both by experience and by trained personnel to carry out such tests.

As to the production of Rh typing reagents, three sources of human serum

are available. First, the accidentally immunized man or woman who has a high-titered serum (in the case of the latter pregnancy being the most common cause for such sensitization); second, the woman who has been sensitized but has low titered antibodies but can be re-

FIGURE 2
Rh SENSITIZATION

stimulated to the production of more potent agglutinins; and third, volunteers, of proper blood type (chiefly Rh-negative, although Rh' and Rh" subjects can also be used) who may be stimulated through injection of Rh-positive blood.

Because of our contact with large obstetrical services (the Blood Grouping Laboratory receives specimens from several hospitals having a combined delivery rate of about 15,000 babies per year), we have been fortunate in being able to obtain fairly frequent contributions from women who have had infants with erythroblastosis fetalis and have high-titered agglutinins at the end of gestation or shortly thereafter. Unfortunately, many of these women are handicapped by anemia, or debility following childbirth, or a combination of these factors, so that not too much blood may be taken at one time. More disturbing is the rather rapid fall in anti-Rh titer which tends to occur in most women within a few months after the end of gestation so that their blood does not remain valuable for too long a time.

It is therefore desirable to have a large panel of donors, either women* restimulated by suitable injections of Rh-positive blood or male subjects initially stimulated and later restimulated so that the useful Rh reagent may be obtained frequently and in sufficient volume.

Our method of stimulation is shown in Chart 2. The first represents the stimulation of volunteer Rh-negative male donors, the second of a female donor originally sensitized through three pregnancies.

An initial stimulation can be produced by as little as 50 ml. of whole blood given intravenously. Intramuscular or subcutaneous blood has not proved satisfactory.

* All such women, subjected to restimulation, should be either beyond the childbearing age or have been sterilized for reasons of health, to avoid harm to future gestations.

The use of a cell-free Rh antigen would be ideal, but to date no uniformly satisfactory free source has been discovered by the many workers in this field, and therefore fresh Rh-positive cells remain the only satisfactory stimulus. They may be given in very minute amounts, to properly sensitize individuals, that is, as little as 0.1 to 0.2 ml. of blood. Larger amounts may be satisfactory, but we have observed disturbing chills, headache, pain in the back, and even fever in highly sensitized individuals from as little as 1 ml. of whole blood injected intravenously.

The production of the rarer typing sera, such as pure anti-Rh' (anti-C) and anti-Rh" (anti-E) and the anti-Hr sera, has not been satisfactory to date, and as the source of these we are still dependent upon the identification of women sensitized by pregnancy with the specific incompatible factor. Here, again, we have been fortunate so that we have available fairly large amounts of the four most useful sera and very small amounts of the two remaining very rare sera.

As to the stabilization of the Rh typing reagents, which tend to deteriorate rapidly *in vitro*, it is obvious that bacterial contamination must be carefully avoided. Unfortunately, the usual bacteriostatic or antibacterial agents, such as acroflavin, the mercurials, and various dyes, cause relatively rapid deterioration of the Rh typing reagent. The early-immune or saline agglutinins are more easily affected than the hyper-immune or albumin forms. It has been necessary, therefore, to avoid such bacteriostatic agents in Rh serum. Refrigeration is necessary for the saline agglutinins though not so important for the hyper-immune forms which are heat-stabile. The latter can often be kept at room temperature for long periods without much loss of potency.

Finally, it has been an unfortunate practice in many laboratories dispensing

these reagents, to dilute them as much as possible, in a natural desire to make a small amount of potent material go as far as possible. This has increased the rate of deterioration almost in direct proportion to the amount of dilution.

As shown in 1944 by Cameron and Diamond, the addition of plasma or serum or, still better, albumin, not only improves the avidity and titer of Rh typing reagents and probably other blood grouping sera, but also stabilizes them by reducing the rate of deterioration. It has become our practice, therefore, to add albumin to all such reagents. This material is preferable to serum and plasma because both of the latter may cause disturbing rouleaux formation, which is not found when albumin is used. A mixture of albumin and serum in the proportion roughly of about 1:1 may help conserve the rather expensive fraction of blood. However, it is important in such instances to use only AB serum or plasma. Bovine albumin is cheaper and just as satisfactory as human albumin.

By the addition of bovine albumin, sera with high titers may be diluted to conserve the reagent and yet avoid rapid deterioration through lowering of the protein content.

Our present method of preparing these Rh reagents is to stimulate the production of high-titered anti-Rh serum by proper injection of Rh-positive cells into Rh-negative sensitized men or women. After bleeding at the most suitable time (often with replacement transfusion in order to prevent depletion of the donor, and allow re-bleeding sooner), the serum is separated sterilely. Quite often, additional Rh typing reagent can be obtained by washing the clot with saline or with a saline and albumin mixture, and allowing settling for 24 hours in the refrigerator. Such sera are then titrated and diluted or fortified to the titer and avidity recently advised by the National Institute of Health.

Thirty per cent bovine albumin is added to the serum during the final dilution, so that the end product has an albumin content of no less than 20 per cent. This permits not only better storage and diminished rate of deterioration, but may increase the avidity of the reagent. The serum may then be stored at 4° C., although refrigeration at -10° and lyophilization or drying in vacuum may be a better method of preservation. To date, we have used only storage at ordinary refrigerator temperature (4° C.) and the sera have shown satisfactory activity many months after first production.

One additional important step is the neutralization of the natural anti-A and/or anti-B isoagglutinin if the donor belongs to Group O, A, or B. This often presents a real problem. To date, we have used chiefly Witebsky's AB substances as prepared first by Eli Lilly and Company and more recently by Sharp and Dohme Laboratories. Proper preparation of saliva from secretor individuals of the proper group may also give suitable AB soluble substances to neutralize such sera. Finally, blood cells themselves may be used, as for example, Group A cells added to the Rh serum of a Group B individual until neutralization of all the anti-B isoagglutinins has been achieved. This is a more difficult and troublesome procedure than the addition of the soluble substances. Complete neutralization must be verified by control tests with Group A and Group B, Rh-negative cells, and such tests must be repeated at frequent intervals, since neutralization does not always seem to be a stable process, particularly where the AB soluble substances have been so used.

DISCUSSION AND SUMMARY

1. In the past five years Rh typing has been recognized as an important and a practical laboratory test. The Blood Grouping Laboratory of Boston has grown at a phenomenal rate since its formation in 1942. Similar labo-

ratories, in hospitals, under the sponsorship of city, county, or state medical groups have been organized all over the country. In fact, it has become an accepted public health responsibility in many states to type all women prenatally, in an effort to protect the Rh-negative individuals from sensitization to the Rh factor, should blood transfusion be necessary during pregnancy or in the puerperium. Certainly such protection, so easily performed, by typing specimens referred to the state laboratory for routine and required serological test of prenatal patients, offers great protection to the individual. In addition, the Rh-negative woman, being so identified, may be watched more carefully by her obstetrician and with suitable testing of the husband and of the patient's blood, particularly in the second or later pregnancy, earlier detection of Rh antibodies may help avoid some of the catastrophes occurring at term to infants with erythroblastosis fetalis. Finally, since large numbers of men, women, and children at some time or other have a serologic test performed in state laboratories, would it not be a simple and protective measure to carry out blood grouping and Rh typing on all such specimens? Through this, the individual, knowing his or her own blood type and Rh factor may help the physician to avoid improper transfusion or blood injection which in so many instances has led to serious transfusion accidents, and in pregnancy cases, to serious harm to infants of sensitized mothers. For all these purposes, the proper use and the increased production of Rh typing reagents are a necessity. Further work is necessary in

order to offer the fullest protection to everyone.

2. The proper use of anti-Rh sera requires that the tests be performed on relatively fresh cells, that certain precautions in technique be observed, that sera for test tube testing on saline-suspended red cells be recognized as different from sera containing the hyper-immune component acting only on cells suspended in plasma, serum, or other protein media, such as albumin. The slide test has proved one of the most satisfactory and most rapid methods of Rh typing. To avoid errors it is advisable that controls be set up, such as known Rh-positive and Rh-negative cells, which can be tested in the laboratory at regular intervals. Under these circumstances, a minimum of errors may be expected.

3. Rh typing reagents, particularly of the standard types, that is, anti-D and anti-C + D, can be obtained from recipients of blood transfusion and from women who have been sensitized through pregnancy. They can be produced in larger quantities by immunizing experimental subjects and by restimulating men and women accidentally sensitized. This is done by injection of the right type and the right amount of Rh-positive blood at suitable intervals. Such sera must then be carefully neutralized to remove their normal isohemagglutinins, diluted to the proper point for required avidity and titer, and stabilized by the use of plasma, serum, or, still better, albumin. For the latter purpose, bovine albumin has been found most satisfactory and cheapest.

Human Waste Disposal from Railroad Passenger Cars*

ABEL WOLMAN, DR. ENG., F.A.P.H.A., AND
LLOYD K. CLARK, F.A.P.H.A.

*Professor of Sanitary Engineering, The Johns Hopkins University, and Consultant
Director, Sanitation Research Project, Association of American Railroads;
and Project Manager, Sanitation Research Project, Association of
American Railroads, Baltimore, Md.*

THE distinguished Professor William T. Sedgwick said in an address¹ before the New England Railroad Club in Boston on November 14, 1899:

I have felt for a good while that we must have . . . some better method of taking care of the excrement . . . of people who are traveling by rail. . . . the present arrangement is unsanitary I confess that I do not today see a . . . practicable remedy. . . . but I believe that the scattering of germs . . . is a serious thing, and sooner or later it has got to be stopped.

At this same meeting, Dr. Samuel H. Durgin,² a past President of the American Public Health Association and at that time Chairman of the Boston Board of Health, remarked that the A.P.H.A. had appointed a committee to submit the best and latest notions for railroad car sanitation to the Association for transmittal to the railroad managements.

Dr. Kenneth F. Maxcy, in a recent report,³ discloses that in 1903 Dr. P. B. Barringer of Charlottesville, Va., in a paper⁴ presented before the Virginia Medical Society meeting, expressed the opinion that infected roadbeds were an unsuspected source in the spread of typhoid fever. He estimated that there were over 370 cases of typhoid traveling over each mile of road in the United

States each year. On this basis he believed that the old roadbeds were permanently infected because the cool moist soil under the ties and ballast provided a natural cultural medium to sustain, forever, the typhoid bacillus dropped in the excrement from persons infected with typhoid fever.

Dr. Barringer's plausible hypothesis apparently received wide acceptance among the sanitarians of his day, despite the lack of convincing evidence. Although some investigators expressed doubt as to its validity, the existence of a sanitary problem was generally recognized.

One of the earliest real issues in which contamination from passenger trains was brought sharply into focus arose in Seattle, Wash.⁵ In 1906 the Chicago, Milwaukee and Puget Sound Railway Company applied to the City Council of Seattle for a franchise to build and operate a railway line along the Cedar River, the source of water supply for Seattle. The City Council was preparing to deed the necessary right-of-way to the railroad company when a storm of protests arose from the local populace, and the mayor was restrained by court action from signing the deeds. The residents believed that the railroad passengers could unduly pollute their drinking water supply.

After preliminary charges were heard, a joint committee was formed to repre-

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

sent all aggrieved parties. Following the report of the joint committee, an ordinance was passed permitting the railroad to be constructed as originally petitioned and regulations were placed in force to control all sources of pollution in the watershed including the railroad.

George C. Whipple⁶ was one of the first to call attention to another important health aspect peculiar to railroad transportation. In his text on "Typhoid Fever" published in 1908, he said: "In some places trains . . . are compelled to have their doors locked. While this prevents contamination of the roadbed, the continual damage to the health and comfort of passengers by reason of deprivation of toilet privileges might easily be a . . . serious matter. . . ."

In spite of these early strictures, however, improvements in railway sanitary devices found their place primarily in regulations concerning them rather than in actual installations. According to Crowder,⁷ the *Interstate Quarantine Regulations* passed in 1894 dealt briefly with disinfection of wastes from sick persons. This was followed by regulatory action by individual states starting with Texas in 1904. The state laws subsequently passed were without interstate coördination, so that one state required what a neighbor state specifically prohibited.

The period from 1912 to 1920 saw many attempts among health agencies to bring about coördinated regulations which were agreeable to all concerned.⁷⁻⁹ Finally a *Standard Railway Sanitary Code* was evolved from the regulations drawn up by the Director General of the railroads during World War I. This code was approved by the Conference of State and Provincial Health Officers of North America and in 1921 the *Code* and the *Interstate Quarantine Regulations* were brought into agreement with each other. During the same year the *Code* was approved by the American Railway Association.¹⁰

The *Sanitation Manual for Land and Air Conveyances Operating in Interstate Traffic* was promulgated by the U. S. Public Health Service on October 2, 1942.¹¹ The *Sanitation Manual* was an enlargement of the *Interstate Quarantine Regulations* of 1921. Finally, the latest revisions of the *Interstate Quarantine Regulations* were published on May 16, 1947.¹²

The many sanitary codes that have been prepared obviously deal with phases of railroad sanitation other than the subject of human waste disposal. All the material reviewed, however, is distinguished by the assumption, unsupported by any epidemiological data, that the discharge of raw feces and urine to the railway roadbeds constitutes a health menace and may spread disease. Dr. W. C. Rucker, then Assistant Surgeon General of the U. S. Public Health Service, was one of the first, and apparently the only person until recently, who publicly questioned this universally accepted hazard. Speaking before a meeting of the Chicago Medical Society in 1914,¹³ he said: "From an aesthetic point of view, the practice (track pollution by interstate carriers) is reprehensible, yet no one has brought forward indisputable evidence that disease is, or may be, generally spread in this way." "Track pollution is undoubtedly a dangerous practice under certain circumstances, and watersheds should always be protected from pollution; however, the knowledge which we have at hand does not indicate that all track pollution results in human disease. What we require first is exact knowledge of the amount of disease spread by track pollution. . . ." "Having that, it will be easy enough to put control measures in operation."

I. JOINT COMMITTEE ON RAILWAY SANITATION, ASSOCIATION OF AMERICAN RAILROADS

The developments which led to the

adoption of the *Standard Railway Sanitary Code* were followed with keen interest by the railroads. Individual lines through their medical departments cooperated whenever possible in the preparation of the regulations. Experience in the building of the railroads had demonstrated the need for sanitary control in railroad operation.¹⁴⁻¹⁸ Indeed, railroads frequently led the way in applied preventive measures, as evidenced by one southwestern railway which inaugurated a comprehensive malaria control program in 1917.¹⁹

The first joint action on the part of the railroads was the appointment in 1921 of a special committee on sanitary matters to consider recommendations of the Public Health Service that ice be separated from the drinking water in the car water dispensers. From this beginning, the committee handled other problems on drinking water supplies, and in 1922 a Joint Committee on Drinking Water Supplies was formally organized. The scope of the activities of the Joint Committee soon enlarged and in 1928 it was redesignated as the Joint Committee on Railway Sanitation. The Joint Committee was made up of representatives of the Medical and Surgical Section and of the Mechanical Division and the Engineering Division of the Association of American Railroads. In addition, representatives were invited from the U. S. Public Health Service and the Department of Health and National Welfare of the Dominion of Canada. The Joint Committee published its first report on railway sanitation²⁰ in 1931, following it later with a supplemental report.²¹

II. REGULATIONS GOVERNING HUMAN WASTE DISPOSAL

Regulations governing the disposal of human wastes from railroad passengers have not changed much over the years. At least as early as 1888, local ordinances required the locking of toilet

room doors in stations and coach yards and while passing through cities and watersheds of drinking water supplies. More recently these restrictions were liberalized to permit the door to remain open upon the condition that retention tanks or soil cans were provided or that the hoppers were directly connected to the sewer.

In the *Sanitation Manual* for 1942 the Public Health Service expressed the belief that the ultimate solution of the problem of sewage disposal on railroad cars would be the permanent installation of retention tanks on the cars to receive the flushings from the toilet hoppers. These tanks would be emptied as necessary when the cars were being serviced in the coach yards, by connection to sewer system inlets. Recognizing the many difficulties involved in such an arrangement, the Service recommended to the Association of American Railroads that the carriers work toward such a goal by experimental and engineering study.

The Joint Committee on Railway Sanitation was of the opinion that the use of retention tanks was open to serious question, especially in view of the mechanical difficulties and the space limitations on the cars. Therefore, the committee proposed a program of research and investigation into the entire problem to find the most suitable means for handling and disposing of sewage wastes. The program was approved by the Association, but action was withheld during the war until January, 1946, when the Consultant Director was retained under whom the work was organized and subsequently directed, personnel was procured, and office and laboratory facilities provided.

III. RAIL CARRIERS AND THE SPREAD OF DISEASE

The first question confronting the Project investigators was the same question posed by Dr. Rucker in 1914;

namely, to what extent have the rail carriers been responsible for the spread of disease? Since the literature discloses virtually no exact data on the subject, Dr. Kenneth F. Maxcy, Epidemiologist, was retained to review all the pertinent evidence and to report upon his findings and conclusions. Aside from the public health implications, some quantitative indication of risk was essential as a basis for further investigation of corrective procedures and devices.

In his study,³ Maxcy reasoned that "if the disposal of sewage along railways has been a public health menace, this fact should be indicated by the unusual incidence of typhoid fever from about 1900 up to about 1920 among persons particularly exposed to this source of infection, (1) by reason of location and residence in proximity to tracks and terminals, (2) by reason of being employed in work on railways, or (3) by reason of being consumers of a water supply which might be polluted by railways at some point in collection or distribution."

With this premise and despite an exhaustive survey, Maxcy was unable to discover convincing evidence that wastes from railroad passengers caused an outbreak of typhoid fever among persons in the three classifications mentioned above for the period 1900-1921. A study of the literature from 1920 to 1945 on all recorded enteric disease outbreaks failed, furthermore, to incriminate sewage wastes from passenger trains. Maxcy's report concludes that "It can be stated with reasonable assurance that information at present available fails to establish the existence of a public health menace resulting from the method of disposal of fecal wastes employed by railways. This by no means proves the negative—that such a menace does not exist. It is reasonable to assume, however, that this practice has in the past been a relatively unimportant route of dissemination of the pathogenic organ-

isms which cause the commonly recognized enteric infections."

It is an interesting commentary on this whole problem that neither the public health agencies nor the railroads had ever authoritatively canvassed this basic hypothesis upon which virtually all the codes and regulations rested. A similar dearth of data on the habits of railroad passengers, data essential to the development of any corrective, parallels the same half century of debate.

IV. STUDY OF EXISTING PATENTS

Inquiries directed to railroads in the United States and Canada, to foreign railways, and to American railroad car builders, disclosed that only one company²² had considered improved methods for human waste disposal to the extent that models were prepared and placed in test. The devices, considered impracticable, did not progress beyond the experimental stage.

When the search turned to the Patent Office, however, this particular field was found to be thoroughly exploited.²³ Inventors have been busy designing new hoppers and methods of treatment and retention almost since passenger trains began running. The patents now in effect may be generally classified as providing for (a) a means for holding the wastes to prevent discharge in stations, (b) disinfection by electrical or steam heaters or by chemicals with and without prior comminution of solids, and (c) incineration of solid materials.

V. INVESTIGATION OF PRESENT DISPOSAL PRACTICES

It was evident early in the Project that development work could not proceed intelligently without a thorough knowledge of existing conditions on toilet use. Careful search revealed that these conditions had never been ascertained previously. The habits of the railroad passenger in the use of toilets and the nature and quantity of the toilet

wastes therefore required detailed field study.

The first investigation,²¹ in 1946, was confined to coach passengers. A similar investigation is now being completed on sleeping cars and overnight coaches on long-distance schedules and on passenger coaches in branch-line use.

The first study was conducted on the cars and trains of the Pennsylvania Railroad. A standard passenger coach was used in the New York-to-Washington schedule during daylight hours, and in the Pittsburgh-to-Washington schedule on an overnight run. A passenger coach with reclining seats was used on the overnight run from Chicago to Washington.

Data were obtained on a total of 30 separate runs. The toilet habits of more than 2,000 persons were studied

while they were traveling a total of 6,251 passenger-hours over a total distance of 320,000 passenger miles.

The men's and women's toilets in each coach were equipped with recording apparatus (Figure 1) which included: (1) a counter to register each opening of the toilet room door; (2) a water meter inserted in the water line to the toilet hopper; and (3) a flush recorder actuated by a mercury switch attached to the flush lever. The flush recorder operated with a chart which showed the individual flush and the length of time the flush lever was depressed. Male and female passengers were counted and recorded on each run after every major station stop. Entries to and exits from the toilets were observed and recorded.

Each test car was equipped with a

FIGURE 1—Arrangement of Equipment on Test Cars

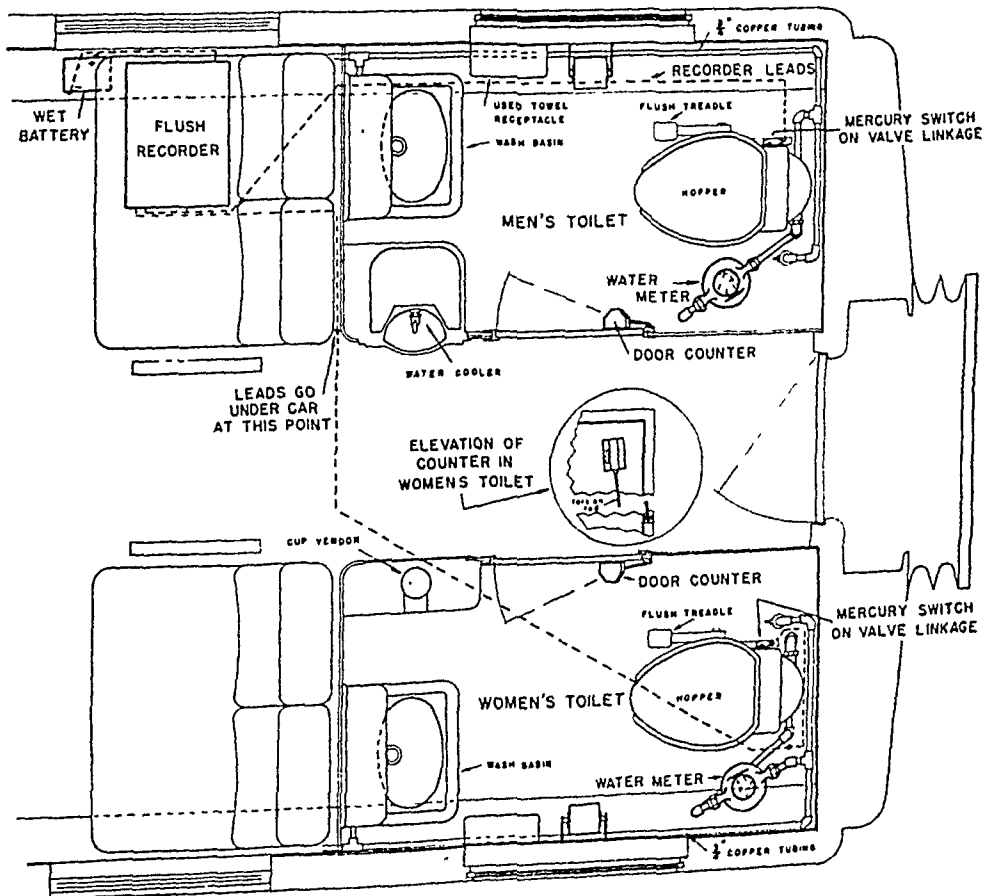

FIGURE 2—Retention Tank Installed in Test Car No. 4241

retention tank to receive all of the material flushed from the toilet hoppers (Figure 2). The retention tank was removed at the end of each run, its contents passed through a grinding mechanism, and an aliquot portion of the macerated material was removed for analysis for solids content.

A. Toilet Room Occupancy

The data obtained on toilet room occupancy (Table 1) on the Pennsylvania Railroad coaches reveal that on the average, the women's room was entered once for every 6.8 passenger-hours. The men's room was entered more frequently—once for every 4.9 passenger-hours. The duration of occupancy for both sexes varied from 1 to 26 minutes, while

| Combined Averages | | | ... | | 8.9 | |

the average was approximately 3 minutes.

The toilet rooms on trains in transcontinental service were occupied more frequently. There was an entry for every 3.5 passenger-hours for both sexes.

For all of the toilet rooms studied the average entry occurred every 11 minutes. The individual passenger entered once every 4 hours.

B. Flushing of the Hopper

Hoppers in the shorter scheduled trains were flushed 701 times in the 30 runs that were studied. This is an average for male and female combined of 8.9 passenger-hours per

flush (Table 2). So far, 6,354 flushes have been recorded on the transcontinental trains—an average of 3.5 passenger-hours per flush.

The duration of the flush—i.e., the length of time the flush lever is depressed—was found to average 3 seconds for all schedules for both sexes.

The interval between flushes for the short schedules was about 27 minutes. Nearly 50 per cent of all intervals between flushes were less than 15 minutes (Figure 3). Ten per cent were greater than 60 minutes.

Only about one-half of the short distance passengers flushed the hopper after entering the toilet room.

| | | | | | | | | | | | | | 21,880 | |
| | | | | | | | | | | | | | 2,390 | |

C. Water Consumption

The quantity of water drawn through the toilet hoppers was less than had been anticipated. An average of only 8 gallons of flushing water was consumed by the test coach in the New York-to-Washington and the Pittsburgh-to-Washington schedules. About 25 gal. were consumed by both sexes from Chicago to Washington. An average of 120 gal. was metered for the overnight coach operating between Chicago and Los Angeles, while the Chicago-to-Portland run averaged about 220 gal.

Although the shorter schedules gave an average of 1.5 quarts of water per flush, as compared with about 1.0 qt. per flush for the cross-country trips, the per-passenger-hour consumption favored the long distance traveler by nearly three to one (0.4 qt. per passenger-hour as compared to 0.15 qt. per passenger-hour). These figures vary widely, however, depending upon the type of flushing valve and the flushing action employed.

D. Nature of Wastes

To determine the nature of the wastes, 1 gal. samples of the captured material, after maceration, were delivered to the National Institute of Health at Bethesda, Md., where solids determinations were made on multiple samples from each of three separate schedules. Two representative samples were delivered to the Blue Plains Sewage Treatment Plant at Washington, D. C., for determination of the Biochemical Oxygen Demand.

Total solids were found to average about 10,000 p.p.m., of which about 60 per cent were soluble solids. There was little variation between sexes. Detailed data are shown in Table 3.

The average of the results of the tests for B.O.D. was found to be 2,100 p.p.m., or a strength of sewage roughly 9 times that of ordinary domestic sewage.

In addition to the normal constituents of the sewage, the nature and number of foreign objects were determined by examining the contents of the retention tanks at the conclusion of each run. The foreign objects consisted of one man's handkerchief, a miniature whiskey bottle, heads of two brass screws, and miscellaneous cigarette and cigar butts, cigarette packages, cigar wrappers, chewing gum, and orange peels.

Interrogation of the servicing personnel in the coach yards revealed that frequent hopper stoppages by foreign objects can be expected. In order to obtain more information on the subject, therefore, a questionnaire was sent to representative railroads throughout the coun-

try. The replies from twenty-nine railroads revealed no fewer than 58 different kinds of objects causing hopper shortages ranging from radiator caps to human fetuses. These objects were classified into the following categories:

| | |
|---------------------|-------------------------|
| Cloth Objects | Bottles and Jars |
| Wearing Apparel | Tin Cans and Containers |
| Leather Articles | Food |
| Paper and Cardboard | Miscellaneous |

E. Quantities of Wastes Discharged

Having determined the content of solids in the toilet wastes and knowing the quantities of water used, the total amount of sewage solids deposited from the test cars to the right-of-way has been calculated.

For the combined total of 701 flushes there was an average weight of sewage solids per flush of 0.026 lb. dry weight (Table 4).

The total sewage solids deposited from the test cars to the roadbed per average hour were 0.121 lb. dry weight. The overall average of total wastes contributed per 100 passenger-hours was 0.258 lb. dry weight.

On the average the test coaches deposited approximately 0.00235 lb. dry weight per mile of track for a single run. Assuming the coach to make one run daily throughout the year, the average yearly deposition per mile of track from a single coach amounts to 0.858 lb. dry

weight. The New York-to-Washington schedule gave results about 3 times greater than this average, due, no doubt, to the crowding of coaches on these trains.

Assuming that the values for the solids content are representative of all toilet wastes from railroad cars, it is interesting to compute what will be the total weight of sewage solids deposited throughout the country from all railroad passengers. Passenger coaches traveling approximately 1 billion miles per year²⁶ at an average speed of 35 miles per hour²⁷ will thus release annually about 3,460,000 lb. dry weight of sewage solids. Spread over 160,000 miles of track in passenger traffic,²⁷ this quantity averages about 0.20 oz. dry weight per yard for coach passengers. Assuming that 65 per cent of all passenger-miles are traveled in coaches,²⁸ the final estimate becomes 0.302 oz. dry weight per yard of track per year.

F. Field Inspection

The quantity of sewage wastes deposited on the roadbed on a country-wide basis seems to be almost insignificant. It is realized, of course, that a great deal of the passenger traffic is confined to specific sections of track. For instance, the Pennsylvania Railroad reports that during 1946 passenger coaches traveled a total of 78,628,188 miles between

* The figure submitted by the National Institute of Health showed solids on the dry weight basis. When sewage solids are deposited to the roadbed in the normal course of operations, however, they contain a high percentage of moisture. Studies in the laboratory indicate that the solids of a representative toilet discharge including feces, urine, and toilet paper average about 86 per cent moisture. This figure was found to agree closely with the figures given by Keefer²⁵ of 77.2 per cent moisture for feces and 96.3 per cent urine, assuming equal weights of each distributed in one toilet use.

New York and Washington. This represents the heaviest through passenger traffic in the United States. At an average speed of 55 miles per hour,* sewage solids from this traffic will amount to about 0.7 lb. dry weight per yard per year. This figure may be increased by about 54 per cent²⁶ to account for other-passenger carrying cars, such as Pullmans, parlor cars, etc., so that the final quantity becomes 1.067 lb. dry weight per yard per year.

The calculated quantities of sewage solids discharged between Washington and New York indicate that at least a certain amount of recognizable feces should be found by actual inspection of the roadbed. Examinations of sections of Pennsylvania Railroad right-of-way on the north and south approaches to Baltimore revealed that on the average there were evidences of 13 discharges per mile containing recognizable fecal matter.

The extent of dispersion of the normal toilet flush from a moving train has been studied to some extent. Examination of the roadbed reveals that when a hopper is discharged at 60 miles per hour, the material will be spread out over a distance of 100 to 150 feet, and over a width of 10 to 12 feet at mid-distance. The fecal matter in the flush is usually confined to a much smaller area, being not more than 30 feet in length and 4 to 5 feet wide. Due to the train speed, the solid matter is usually found plastered against the exposed side of the ties which face the oncoming train.

Not all of the flushed material reaches the roadbed. As many car repairmen will testify, a goodly portion is thrown against the undercarriage of the car and on the steps if they are non-retractable.

G. Bacteriological Examination of Ballast

A limited bacteriological examination has been conducted on the ballast taken from the Pennsylvania Railroad trackways near Baltimore carrying heavy passenger traffic. Samples were taken from the surface of the ballast and from depths of 6 to 12 inches and examined for the presence of coliform organisms. Preliminary results show that 50 per cent of the surface ballast supported no coliform growth, while the remainder gave counts of approximately 4 coliform organisms per sq. cm. of surface area of stone. The subsurface ballast gave positive results for coliforms in all samples, 80 per cent of the samples showing counts of fewer than 50 per sq. cm. of surface area. This ballast has

been in service about 10 years according to the railroad authorities. Similar examination of five samples of new unused ballast gave all negative results.

VI. PRESENT STUDIES

Simultaneously with the study of the existing methods of toilet waste disposal and the use of toilet facilities, the Project has experimented on a great many treatment methods and devices. These efforts have been directed toward programs for comminution and disinfection.

Subdivision of particles was considered desirable not only to simplify the disinfection process, especially if disinfection is to be accomplished by heat, but also to convert feces, paper, and cloth articles into a sufficiently finely divided state to reduce visibility on controlled discharge at high train speeds. Such a device must be rugged because of metal and glass objects; it must be small and a low power-consumer. The search is continuing for the ideal grinder, but a commercial unit exhaustively tested in the laboratory has been installed on a hopper on a test car of the Pennsylvania Railroad operating between New York and Washington. So far it has proved satisfactory operating under summer conditions.

Extensive research has revealed that disinfection of macerated toilet wastes by heat is well within the realm of practicability. Much experimentation remains to be done on the preferred methods of applying the heat, but the source of heat is apparently sufficient when supplied either by electrical means or by steam, or by a combination of the two. These means are being employed in a test apparatus mounted on the Pennsylvania car carrying the grinder. Although sufficient data are not available at this time to warrant conclusions, it may be stated that a temperature not exceeding 160° F. and a holding time of not more than a few seconds will produce the desired negative coliform results.

* Based on P.R.R. timetables

Because of infrequent use the railroads might not feel justified in the purchase of treatment units for hoppers in coaches on branch lines. For such conditions consideration is being given to the development of a simple receptacle to hold all of the flushings until the terminal is reached, where receptacle and contents might be destroyed. For some conditions holding in stations may be all that is necessary. Certainly one cannot escape the conviction when traveling through the great unpopulated expanses in the West that discharge of human wastes, treated or raw, would have little effect on the local morbidity rates or on potential hazards.

The results of further laboratory and field studies will be released at intervals by the Project. In the meantime, direct consultation with public health agencies, professional groups, and others proceeds in order to correct, as rapidly as possible, aesthetic and public health hazards in the disposal of human wastes in railroad transportation.

ACKNOWLEDGMENT — The data presented herein have been obtained through the co-operation and assistance of the Pennsylvania Railroad, the Baltimore and Ohio Railroad, the Joint Committee on Railway Sanitation, and officers of the Association of American Railroads.

The detailed accumulation, calculation, and tabulation of the data in the studies on patents, toilet use, and nature of wastes, ballast and right-of-way deposits are primarily the accomplishments of the following members of the Sanitation Research Project: William A. Hazlett, Mechanical Engineer; Frederick G. Whelan, Electrical Engineer; Patrick N. Owens, Assistant Sanitary Engineer; and Ralph F. Vaccaro, Bacteriologist. The burden of typing, proofreading, and editing has been carried by F. Marie Ridley, Secretary, and Clara-Louise Kuehn, Laboratory Assistant.

Health Education Workshop

Notice of the following health education workshops has come to the *Journal*:

Western Reserve University, June 21-July 31, limited to 50 men and women from the educational field (teachers and nurses). Course will grow out of the problems presented by the individuals at the first session on June 21. Director, Charles F. Good, M.D., Director of Cleveland's School Health Service and pediatrician in Western Reserve Medical School and University Hospitals. Tuition, \$84. Credit, 6 semester hours. Apply for admission 1 month before registration to Graduate School, Western Reserve University, Cleveland, Ohio.

Yale University, Graduate School, Department of Education. June 26-August 6, plus 2 weeks for preparation of term papers. Seminar in secondary school education designed particularly for teachers responsible for teaching or organizing high school health education programs, using workshop techniques. Director, Charles C. Wilson, M.D., Professor

of Education and Public Health, Yale University. Tuition \$120. Scholarships available. Credit, one-fourth of a year's work or 8 points. Apply Clyde M. Hill, Chairman, Department of Education, Yale University, New Haven, Conn.

George Williams College, Lake Geneva Campus. College Camp, Wis. July 6-31. Is a workshop in education for health and fitness designed for teachers, community workers, nurses, and others interested in health? Tuition and living expenses \$165 and up. Scholarships available. Credit, six quarter hours. Apply Arthur H. Steinhaus, Director of the Workshop, George Williams College, Chicago 15.

University of Cincinnati, June 21-26. Faculty includes Dr. Helen L. Poops, Health Coördinator. One hour of credit as an auditor with an additional hour upon successful completion of assigned field work. Apply Dr. Spencer Shank, Dean, Summer School, University of Cincinnati, Cincinnati 21, Ohio.

Essentials for the Control of Ragweed*

ISRAEL WEINSTEIN, M.D., F.A.P.H.A., AND
ALFRED H. FLETCHER, F.A.P.H.A.

Commissioner of Health†; and Director, Bureau of Sanitary Engineering, City Health Department, New York, N. Y.

IT has been estimated that there are over 3,000,000 persons in the United States who suffer from hay fever caused by ragweed. The U. S. Public Health Service, in a leaflet on hay fever, states that ragweed grows in sufficient quantity in much of the territory east of the Rocky Mountains to produce symptoms of ragweed hay fever in an estimated 2 to 3 per cent of the inhabitants of the area. It is generally recognized by allergists that its prevalence has been steadily increasing from year to year. In a report on chronic diseases taken from the data collected in the National Health Survey conducted by the U. S. Public Health Service during 1935 and 1936, "hay fever and asthma" stood fourth in prevalence in a list of chronic diseases and was exceeded only by rheumatism, heart disease, and arteriosclerosis and high blood pressure. In this list, hay fever and asthma exceeded such chronic diseases as hernia, chronic bronchitis, cancer and other tumors, tuberculosis, diabetes mellitus, and others.

Thommen¹ estimates that pollen asthma occurs in about 35 per cent of all hay fever subjects in the New York area, and Huber¹ reports that pollen asthma occurs in about 54 per cent of the Chicago hay fever sufferers.

The discovery of the herbicide, 2, 4-dichlorophenoxyacetic acid opened a new field in public health by making it possible to eliminate ragweed from vast areas at a reasonable cost, only a fraction of that required for mosquito control.

Ragweed hay fever, then, can be said to be a fairly common disease and the weapon to control it is now available. It should, therefore, receive the attention of governmental authorities as a public health problem. R. P. Wodehouse, who is probably the best informed botanist on the subject of ragweed and its control, expresses his feelings on the subject in a letter written in 1939 to one of the authors as follows: "Hay fever can be cured by treating the environment instead of the patient. In fact it is the only way that it ever will be cured."

Before outlining the New York City ragweed control program, some of the essential knowledge necessary to bring about control of ragweed will be discussed.

For the past 25 years a considerable amount of information has been accumulated on the concentration of ragweed pollen in the air. One of the outstanding contributors is O. C. Durham² of Chicago. Much of this work has been done in response to the demand for information on the part of allergists and hay fever sufferers. The United States has been fairly well covered in a general

* Presented before a Joint Session of the Engineering and Industrial Hygiene Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

† Now Director, Bureau of Health Education.

way by data collected from a number of stations, made possible by the coöperation of the U. S. Weather Bureau. Maps are available which divide the United States into regions in accordance with the variations in the amount of ragweed pollen in the air, as shown by these spot checks.

In order to use the pollen content of the air as a device for evaluating ragweed control programs, it is necessary to plan the location and number of pollen sampling stations so that an adequate picture of the variation in pollen content throughout the areas can be obtained and accurate related meteorological and ecological data accumulated. It is possible that in the early stages of the development of ragweed control programs, the weather may have a greater influence on the pollen content in an area than the elimination of some of the ragweed plants. As ragweed control programs become effective over large areas, there will be a need for sufficient data to explain the presence of, or the year-after-year reduction in the ragweed pollen content in areas where the ragweed plants have been reduced in number or eliminated. It will not be sufficient to have the results of one or two stations used as an index of the completeness of a ragweed elimination program over an extensive area any more than one or two adult mosquito traps will serve as an index of the effectiveness of a mosquito campaign. It is recognized that there is a considerable difference between the distribution of adult mosquitoes from a source of breeding and the distribution of pollen from an area of ragweed plants. An air pollution survey in 1936 conducted by the New York City Health Department indicated a considerable variation in the pollen content of the air in the 5 boroughs of the city and this variation was related to the amount of vacant area in those boroughs.

In response to a demand for stand-

ardization of procedures in pollen collecting and counting, the American Academy of Allergy³ several years ago appointed a National Pollen Survey Committee to study and recommend standards for pollen collecting and counting. A preliminary report of the work of this committee has already been published which includes the recommended standards.

A group of allergists⁴ in the Division of Allergy of the Jewish Hospital of Brooklyn, in collaboration with the Pollen Survey Committee of the American Academy of Allergy, conducted studies during 1946 and 1947 in an attempt to shed some light on the influence of ragweed control programs on the pollen content of the air. They outline the reasons for their studies as:

1. To determine the relative ragweed pollen concentrations in various boroughs
2. To determine whether the pollen counts of Brooklyn and Manhattan, the only boroughs studied in the past, have been representative of the entire city
3. To determine to what extent ragweed pollination in surrounding communities influences New York's pollen problem
4. To collect data which might help to determine the effectiveness of the ragweed extermination campaign which is being carried on by the Department of Health in this city
5. To obtain further data on the relationship of meteorologic conditions to pollen counts

The plants, *Ambrosia artemisiifolia* and *Ambrosia trifida* (short and giant ragweed) are the principal cause of autumn hay fever. Ragweed pollen is buoyant, abundant, and has high allergenic toxicity. The seeds, which are dropped close to the plant are disseminated by water, animals, and man. They are heavy and do not ordinarily move far from the plants which produced them. Ecologists classify plants into 3 general categories: pioneer, intermediates, and climax vegetation. This natural phenomenon is known as plant succession. Pioneer plants⁵ are able to grow on barren soil serving as nature's

rescue squad to prevent the total waste of top soil. The most important pioneer plant is the ragweed. Where these pioneer plants are able to establish themselves they flourish over a period of years until they are able to restore the soil so that it will support an intermediate group of plants such as the late weed and grass plants. This process may take 10 or more years. As the intermediate plants establish themselves, the pioneer plants are forced out by competition. The ragweed plant is not only a pioneer; it is also a non-competitive plant. If left alone, this intermediate stage would then give way to climax vegetation. Only selected areas are ever allowed to return to climax vegetation. According to Wodehouse, the Indians had no hay fever because they lived in the primeval forest or on the native prairies. In those early days the land was clothed with climax vegetation. As the white man built cities and towns cutting down the forests and developing farms and highways, climax vegetation was removed and much of the soil was left bare. Hay fever is nature's reply to man's wasteful exploitation of natural resources.

Little is known of the ecology of the ragweed plants. A number of problems are already arising in connection with developing the most effective program of control. A study of the reaction of plants to the use of 2, 4-D on such a wide scale as practised in New York City during the past 2 years promises to develop some of the unknown facts.⁶ Ragweed plant ecology is as important to the future ragweed control programs as entomology has been to programs to all insects.

area, I am puzzled as to the asthmatization from a letter received in the Chicago public health official indicating how easy it is to make mistakes in a question about which lit-

found in New York City and I am certain that within a radius of at least 10 miles of Fifth Avenue and 42nd Street there is no ragweed. The question therefore arises whether the pollen which is transmitted by wind from rural areas might not be more important in causing hay fever than that which grows within the bounds of a city."

Actually there were approximately 500 acres of ragweed growing in Manhattan. Within a radius of 10 miles there was probably as heavy a growth of ragweed as could be found in any similar 10 mile radius in this section of the country. In many sections of the country, as in this area, ragweed is an urban problem even more than a rural problem. Many of the projects built by man which remove plant cover from an area take place in cities, where farms are being abandoned and subdivided for development, where streets are being built without finishing the curbs and sidewalks, where rain run-off is being concentrated more rapidly in natural drainage ditches. Rural areas in general are more stable except perhaps along the highways. They may not be the main problem as visualized by health workers who have not tackled the problem of control in earnest.

Several years ago the selective herbicidal properties of the potent plant-growth-regulating substance 2, 4-dichlorophenoxyacetic acid (2, 4-D) and its derivatives were discovered. In 1945 sufficient quantities of this chemical became available.⁷ Thirty to 40 different manufacturers offered 2,4-D in the form of salts, esters, and related derivatives which, in a concentration of 0.1 per cent by weight, would kill broad leaf plants but not grasses and other resistant plants. The herbicide is absorbed by the plant, transferred to the lower stem and roots, causing the plant to starve. The first symptoms are bending and twisting of stems and leaves followed usually by swelling, cracking, and split-

* Presented before the American Association of Public Health Officials, Atlantic City, 1947.
† Now Director, Bureau of Plant Industry, U.S. Department of Agriculture.

ting of the stems, yellowing, browning, and drying up. The roots become spongy, enlarged, and water soaked.

The New York City Department of Health⁶ studied the possibility and practicability of using this herbicide to control ragweed on a city-wide basis. Two demonstrations showed that when it was applied as a 0.1 per cent solution, wetting about 90 per cent of the plant foliage, it would kill the weeds without injuring the grasses. Approximately 200 gallons were found to be necessary for one acre of ragweed and 1 crew, consisting of a spraying unit and 3 men, could spray approximately $2\frac{1}{2}$ acres a day. Approximately one pound of 2, 4-D powder makes 100 gallons of the 0.1 per cent herbicide solution, bringing the cost of chemical to about \$2 an acre; 2, 4-D has certain advantages over chemicals that have been used in the past. It is non-corrosive, non-inflammable and will not explode. In addition, it is not poisonous to human beings.

Ragweed plants shed their pollen early in August and produce seeds a short time later. In order to obtain maximum benefits, the plant should be destroyed by the early part of August so as to prevent the shedding of pollen or the dropping of seeds. Ragweed is an annual plant, therefore, if all the plants were destroyed in any one year, there would be no ragweed seeds dropped to produce plants in future years. It is possible to destroy all of the ragweed seeds produced in an area that is properly sprayed in any one year. However, it is impossible to destroy all the ragweed seeds in existence as a small proportion of each year's crop of seeds remains viable in the soil and a few of these will grow when the soil is disturbed, exposing the seed. The number of plants growing from old seeds is small compared to the total annual crop of seeds once the ragweed plant has become generally established in an area.

The number of plants coming from the old seeds depends on the amount of soil which is disturbed by the abandoning of farm land and the barren soil left along the sides of new roads and areas where the cover crop is laid waste and the surface remains bare.

Experience indicates that the selective action of the herbicide hastens plant succession by killing the ragweed plant. It seems to encourage the growth of the intermediate plants, namely, late weeds and grasses. Indications are that the spraying of the ragweed plant aids in building soil. Extensive areas where both ragweed and other plants were growing, which were sprayed in the 1946 campaign, produced a solid growth of grasses and other plants during the season of 1947. The spraying not only killed the ragweed plants of that season, but hastened the phenomenon of plant succession, establishing the intermediate stage of plants which not only controls erosion but discourages the growth of the ragweed, a non-competitive plant.

Attempts to enforce city laws requiring property owners to destroy ragweed on their property have been not only costly in time consumed but also ineffective. Many property owners could not be located and others could not be induced to eliminate the weeds in time to prevent the spilling of pollen and the production of seeds. Centrally directed campaigns to eliminate seeds by cutting and grubbing on a city-wide basis, although more successful, have generally failed because of the cost and the fact that much of the work accomplished did not always prevent pollination. Plants grew back and pollinated and produced seeds in a few weeks' time. Wherever the soil was disturbed, dormant seeds were given an opportunity to germinate.

Much can be done to support a city-wide spraying program by securing the coöperation of property owners in eliminating ragweed from their property, particularly when they are living on it or

This was an all-day conference and was attended by over 200 people including professional botanists, municipal and other official representatives of garden clubs. The Commissioner of Health of New York City called meetings of health officers and municipal officials from the metropolitan area to discuss the use of 2, 4-D for the control of ragweed. The Department of Health believes that within the next few years it will be possible to eliminate practically all the ragweed plants within the city limits, and every effort will be made to

extend the ragweed control program throughout the metropolitan area.

Maternal and Child Health Training Program

The Johns Hopkins University School of Hygiene and Public Health has established a specialized program in Maternal and Child Health. Its "purpose is to provide advanced training for a limited number of special students in the broad field of Maternal and Child Health with emphasis on the integration of administrative, clinical, and preventive skills and with attention to current developments and trends in medical care. It is particularly adapted to the needs of administrators of Maternal and Child Health and crippled children's programs and of qualified individuals who wish to make a combined career as full-time consultant and administrator in the obstetric or pediatric

services of health departments or other agencies."

Students taking this work are expected to spend 11 months in residence, an 8 month academic year including the required courses for the Master of Public Health degree, and a summer period devoted to field and clinical work. Clinical facilities are provided through arrangements with the pediatric and obstetric services of The Johns Hopkins Hospital and the Maryland State and Baltimore City Health Departments.

The first small group of students is now in training. Further information can be secured from Paul Harper, M.D., Maternal and Child Health Division, 615 N. Wolfe Street, Baltimore 5, Md.

Comparative Efficiency of Rectal Swabs and Fecal Specimens in Detecting Typhoid and Salmonella Cases and Carriers*

HOWARD J. SHAUGHNESSY, PH.D., F.A.P.H.A., FRANCES FRIEWER AND ADELE SNYDER

Division of Laboratories, Illinois Department of Public Health, Chicago, Ill.

IN bacillary dysentery the causative organisms are known to be confined chiefly to the lumen and especially to the superficial ulcerations of the large intestine. The ideal method, therefore, for collecting material from cases or carriers of bacillary dysentery for bacteriologic examination would seem to be the application of a swab to the ulcers or inflamed intestinal mucosa while they are being visualized through the sigmoidoscope. This procedure is time consuming and requires the services of a specially trained physician. The development of the "blind" rectal swab technique in which a swab is passed into the rectum either directly¹ or through a lubricated rubber tube² has made it possible to collect large numbers of specimens rapidly and to permit the inoculation of culture media without any delay. The superiority of the rectal swab specimen over the passed specimen in the laboratory diagnosis of bacillary dysentery has been demonstrated or indicated by several groups of investigators.³⁻⁸ In this laboratory the use of the rectal swab has become routine in the investigation of dysentery outbreaks.

Because of the rapidity and simplicity with which the rectal swab procedure can be employed, it would be desirable if it could be adapted to surveys made for the purpose of finding cases or carriers of typhoid or *Salmonella* infections. However, it is well known that the excretion of these organisms is from the small intestine and adnexa and not from the lower bowel. There are usually no ulcerations or other lesions of the lower bowel in which the bacilli are harbored and from which they can be cultured. The investigation reported here was, therefore, undertaken to compare the efficiency of the usual type of passed fecal specimen with the rectal swab in the laboratory diagnosis of typhoid and *Salmonella* infections.

The large group of typhoid carriers confined in special wards at the Manteno State Hospital, Manteno, Illinois, provided excellent material for the study. Through the coöperation of the hospital authorities 43 patients, with histories of a typhoid or *Salmonella* carrier state, were made available for the study. The patients were selected, on the basis of previous information, so that persistent intermittent and infrequent shedders were all represented in the group studied. Pre-cathartic rectal swabs and

passed specimens were collected from each patient on the same day. In the evening of the same day the patients were given bile salts and on the following day a saline cathartic was administered. Two rectal swabs and a passed specimen were collected from each patient after the first bowel movement had occurred. An attempt was made to collect six series of pre-cathartic and post-cathartic specimens from each patient. This was not always possible. It was especially difficult to obtain the desired number of pre-cathartic passed specimens from this group of psychotic patients.

Preliminary studies had shown that the best results could be obtained by culturing the rectal swabs in accordance with the following technique: As soon as the swabs were collected, one swab from each patient was plated on Hajna-Perry agar and the other inoculated into a tube containing 2-3 ml. selenite enrichment medium. On the following morning the growth from the latter was streaked on to S. S. medium. In one series the first swab collected was plated directly and the second placed in enrichment medium. This procedure was reversed in alternate series.

The passed fecal specimens were handled according to the following technique: The specimens were collected in paper containers; as soon as specimens were delivered to the laboratory (all were received and plated within 2 hours after collection except a series delivered to our Chicago laboratory for comparative purposes), they were streaked on Hajna-Perry agar and a heavy seeding made into a 12-15 ml. tube of selenite enrichment. On the following morning material from the enrichment media was streaked on to S. S. medium.

Any plate showing suspicious colonies was set aside for further examination. When suspicious colonies were seen on a plate, two or three were picked for further study. Isolated cultures were

subjected to extensive biochemical tests and were tested against high titer specific agglutinating sera. All salmonellas isolated were typed.

It should be emphasized that the work was handled in a volume and under the conditions that would be encountered in a survey done in connection with an actual outbreak. Plates were picked without knowledge of the patient's name or what the parallel series of plates revealed. All plates were compared after the picking was completed.

The complete findings are shown in Table 1. From a mere inspection in this table it is apparent that none of the methods is markedly superior when specimens from heavy shedders are examined. However, when the specimens apparently contained few organisms as in those from patients 2, 3, 5, 15, 18, 23, 24, 25, 26, 27, 28 and 39, the efficiency of the passed specimen appears to be greater than the rectal swab. In these instances, also, it appears that the post-cathartic passed specimen yields a higher

percentage of positives than its pre-cathartic counterpart.

The media analyses presented in Tables 2, 3, 4, and 5 are based on the rectal swab results from the laboratory set up at Manteno and the passed specimen findings from our Chicago laboratory. The Chicago laboratory results were used in the latter series because they more nearly approximate the conditions under which specimens are usually received in a public health laboratory. These findings demonstrate again that no single medium is able to pick up all enteric pathogens. They also demonstrate the value of an enrichment medium such as Selenite F.

Because it was impossible to obtain all of the specimens planned, the crude data shown in Table 1 do not present the best comparison of our findings. In Tables 6 to 10 comparison is made of only those specimens which could be definitely paired. In these tables the results from the tetrathionate enrichment series are omitted. Chi-squares have been calculated on all pairs and p-values are shown under each table. All of the differences point in the same direction, i.e., in favor of the passed specimen and those taken post-cathartic, but only one difference is statistically significant, that between the pre-cathartic rectal swab and the post-cathartic passed specimen. The latter comparison is the one of greatest interest to us because the rectal swab is commonly used on patients who have not been given a cathartic while post-cathartic passed specimens are recommended in this type of survey. The marked superiority of the post-cathartic specimen over the pre-cathartic rectal swab under these conditions is striking.

It may be argued that these results may not be conclusive since they were obtained on known carriers. Several months after this part of the study was completed an opportunity presented itself to make another study under field conditions. A case of typhoid occurred

in an institution for mental diseases at K. and the patient was transferred to the institution hospital. The 189 patients on the ward from which this patient was removed were divided into two approximately equal groups. On August 9, 1946, the patients in group one were examined by the rectal swab technique while post-cathartic passed specimens were collected from those in group two. Three days later rectal swabs were collected from the latter group and post-cathartic passed specimens from those in group one. *Eberthella typhosa* was isolated from 7 individuals. From all patients with negative findings two more post-cathartic specimens were collected, all of which gave negative findings.

Analysis of the findings showed that only 3 of the 7 cases or carriers found in this survey yielded positive rectal swab specimens. One of these positives was obtained on a post-cathartic rectal swab, taken through error. All of the original group of post-cathartic specimens on these 7 patients were positive.

Subsequently, beginning about 12 days after the original specimens were collected, two sets of pre- and post-cathartic passed specimens were collected from each of the 7 typhoid cases or carriers found in the original survey. All of the post-cathartic specimens except 1 were found to be positive while 4 of the pre-cathartic specimens were negative. It was noted that the findings were usually positive on all three media combinations employed (S. S., Selinite-S. S. and Hajna-Perry) when post-cathartic specimens were examined, whereas with pre-cathartic specimens positive results were more often obtained, if at all, on a single medium.

DISCUSSION

It is apparent from the results shown above that the post-cathartic passed specimen of feces is a much more satisfactory source of material for bacterio-

logic examination for typhoid bacilli and salmonellas than the rectal swab although the latter is apparently better as a source of shigellas. This difference might have been predicted from the fact that shigellas are believed to flourish on and in the upper layers of the mucosa of the lower bowel where they can be easily collected by the rectal swab while, on the other hand, *E. typhosa* and the salmonellas are thought to be excreted largely from the small intestine and gall bladder.

By the time typhoid bacilli or salmonellas reach the area which can be reached by the rectal swab they are probably well distributed in the fecal mass. Thus, the rectal swab picks up only a few of these pathogens unless the case or carrier is a very heavy shedder. Enrichment does not aid greatly because the amount of fecal material on the swab is not large in comparison with the amounts of the passed fecal specimen usually employed in seeding the enrichment media.

The effectiveness of both rectal swab and passed specimen was increased in this series if the patient had had a cholegogue and saline cathartic before they were collected. However, in the Manteno study the number of carriers found in the pre- and post-cathartic rectal swab series was identical because carriers found in the pre-cathartic series with the rectal swab technique were missed in the post-cathartic rectal swab series and *vice versa*. However, 11 more carriers were found in the Manteno post-cathartic passed specimen series than in the pre-cathartic group collected by the same technique. On the other hand, 3 of the pre-cathartic passed specimens yielded positives not found in the post-cathartic passed specimen series, so there was a net balance of 8 carriers in favor of the post-cathartic passed specimen series over the similarly collected pre-cathartic series. This was due in large part to the greater number of post-

cathartic specimens that were obtained.

The advantage of the post-cathartic passed specimen over its pre-cathartic counterpart was not significant when paired specimens were studied. In the examination of paired specimens collected during the K. outbreak studied by us, there was again found to be a slight balance in favor of the post-cathartic over the pre-cathartic passed specimen in the ratio of 13 to 10. The difference is again greater than suggested by the figures because inspection of the data shows that the positive findings in the pre-cathartic series were usually found on fewer media combinations, often only one, than in the post-cathartic series.

While the post-cathartic rectal swab yielded much better results than the swab employed without prior administration of a cathartic, we do not believe from our experience that the post-cathartic rectal swab is practicable for general use, especially in psychotic patients. The employment of this procedure in persons who have had a cathartic is disagreeable and, in our opinion, dangerous to the collector of the swab.

The post-cathartic passed specimen has one further advantage over the rectal swab in the laboratory diagnosis of typhoid and salmonellosis. The rectal swab must be cultured immediately after collection in order to prevent drying and, therefore, cannot be used to transport specimens to a distant laboratory by the usual modes of transportation. The post-cathartic passed specimen can, however, be cultured after a considerable delay without loss of efficiency. For example, 205 paired specimens of this type were examined at Manteno State Hospital by one of us (F. F.), and at our Chicago laboratory by another (A. S.) after shipment by Railway Express. The fresh specimens yielded 78 positives while the shipped specimens gave 80 positives. This difference is, of course, ascribable to chance since it

would not be expected that the delay would improve the specimens.

The rectal swab can, we believe, be used successfully for one purpose in typhoid and salmonella laboratory work. As indicated above, it was about as effective as the passed specimen in finding heavy shedders of these pathogens. It appears to us that, because of the simplicity and rapidity of the rectal swab procedure, it might well be used as a preliminary to other methods in any large-scale surveys designed to find carriers of enteric pathogens. Used in this way the rectal swab may make it possible to find quickly and easily almost all of the heavy shedders of *E. typhosa* or *Salmonella*. Additional post-cathartic passed specimens can be used to detect the infrequent or light shedder of these organisms. This plan has been adopted by the Illinois Department of Public Health for routine and emergency surveys of institutionalized populations.

SUMMARY AND CONCLUSIONS

Post-cathartic passed specimens are more efficient than rectal swabs as a source of material for the laboratory diagnosis of typhoid and salmonellosis or of the carrier state in these diseases.

The rectal swab is, however, effective in the detection of heavy fecal shedders of *E. typhosa* and *Salmonella* and may be of great value in rapid screening of large population groups if combined with subsequent examinations of post-cathartic passed specimens.

Susceptibility to Typhus of Rats on Deficient Diets*

FLORENCE K. FITZPATRICK

Medical Research Division, Sharp and Dohme, Inc., Glenolden, Pa.

THE observation that there is increased mortality in epidemic typhus when this disease manifests itself in malnourished populations is almost as old as the history of typhus. Despite the antiquity of this observation, almost no experimental work correlating diet and susceptibility to typhus has been done. Some years ago Zinsser and coworkers¹ showed that rats and guinea pigs deprived of all vitamins evinced a greatly increased susceptibility; and Pinkerton and Bessey² reported that riboflavin deficiency similarly lowered the resistance of the rat to typhus. More recently, Macchiavello³ has shown that vitamin C deficiency in the guinea pig also increases susceptibility. In the first two reports the number of animals used was very small and the composition of the diets uncertain in the light of our present knowledge of animal diets.

Various possibilities present themselves as explanations for the observed effect of malnutrition on resistance to typhus in human populations: Resistance might be affected by such factors as the inadequate intake of one specific food factor—protein or a vitamin—or by a low total calorie consumption, or by a diet in which there is a multiple deficiency involving several vitamins.

The work here reported represents

part of a study of the effect of various diets on susceptibility to typhus in the rat in which we have attempted not to produce extreme deficiencies, but rather to mimic dietary conditions as they exist or might exist in human populations in various parts of the world.

METHODS AND MATERIALS

Weanling male rats of the Wistar strain were used. Their weights at the start varied between 35 and 60 gm., and they were selected so that the average weights of groups on various diets in the same experiment were the same. Twelve or more rats were placed on each diet. They were housed in individual cages with screened bottoms in an air conditioned room at a temperature of 70 to 74° F. The basic diet was composed of vitamin test casein, sucrose, "Crisco" or "Primex," corn oil, "Cellu" flour, Jones' salt mixture No. 12, choline chloride, vitamin K, and "Oleum percomorphum." The vitamins of the B group were at times included in the ration and at others administered separately as a solution, depending upon the nature of the experiment. In the latter case, they were prepared so that 1 ml. of solution contained the total daily requirement. When rats on a natural diet were used in an experiment, they were fed a mixed ration of oats, Rockland diet, and fresh vegetables.

With a few exceptions, an arbitrary period of 6 weeks on the various diets

* Presented before a Joint Session of the Food and Nutrition and Laboratory Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

was selected. At the end of this time, in most instances, two-thirds of each group of rats were infected with 1 ml. of murine typhus yolk sac suspension by the intraperitoneal route, while the rest were kept as diet controls. The infectious material was preserved frozen in 1 ml. samples at a temperature of minus 40 to minus 70° C. Its titer was checked by infecting a few control rats on the natural diet or on the complete synthetic diet about a week before the deficient rats were to be infected. For some experiments an infectious dose which killed none of the controls on the preliminary test was selected in order to show up any increased susceptibility in deficient rats. In other experiments, an infectious dose which was lethal to 50 per cent or less of the animals tested was employed. When death occurred in deficient rats, smears of peritoneal exudate, stained by the Macchiavello method, were examined to obtain confirmation that deaths were due to typhus. These usually showed numerous rickettsiae. (It has been reported in the literature that endemic typhus is never a fatal disease in normal rats. This observation was made before the development of methods for the cultivation of rickettsiae in large numbers, and is no longer correct. We have found, using infected yolk sac suspensions, that it is possible, depending upon the dilutions used, to kill rats or to produce an

infection from which they recover. Susceptibility decreases with age. When an infection is severe, even when it does not end fatally, rats exhibit a listlessness, anorexia, and marked loss of weight. There may also be "spectacle eyes" and porphyrin whiskers giving the appearance of vitamin deficiency. These symptoms can be observed even in well nourished animals. It is perhaps possible that the rapid multiplication of rickettsiae takes place at the expense of a vitamin, or vitamins, in the host.)

RESULTS

1. *Low Protein and Low Vitamin Diets*—It seemed advisable at the start to determine whether a diet low in protein but otherwise complete, or a diet low in vitamins of the B group but adequate in other respects was more important in reducing resistance to typhus. Four groups of rats were, therefore, fed the following diets *ad lib.*: (1) low protein, adequate vitamins of B group; (2) low protein, low vitamins; (3) adequate protein and vitamins; (4) adequate protein, low vitamins. Choline and vitamins other than those of the B group were fed in adequate amounts to all rats. The compositions of these diets are shown in Table 1. As was to be expected, rats receiving the 5 per cent protein ration did not do well. They either gained very little or fell below their initial weight by the end of the 6 weeks

period. This occurred whether adequate vitamins were present or not. The gain of rats on the complete diet (diet 3 in Table 1) was between 70 and 120 gm., while rats receiving adequate protein and low vitamins (diet 4) gained between 25 and 40 gm. This experiment was performed four times. As will be seen from the two experiments shown in Tables 2 and 3, deaths commenced to occur on the third or fourth day after intraperitoneal injection with murine typhus. The difference in susceptibility of the rats on diets 1, 2, and 4 was not striking, whereas the rats on the complete diet (diet 3) showed a much higher resistance. This was found to be partial or complete depending upon the strength of the inoculum.

ficiency of protein or of B vitamins each appeared to increase susceptibility. It was realized that the rats receiving the deficient diets ate less than those supplied with a high intake of protein and vitamins, and that paired feeding experiments would be necessary to rule out the effect of inadequate food intake.

To this end, 2 groups of 12 rats each were placed on diets 3, and 4, as in the experiments just discussed, but with two changes: First, the rats receiving diet 3, the complete diet, were given *double* the quantity of vitamins of the B group (exclusive of choline) in their diet; and second, they were pair-fed with rats fed diet 4; so that in this experiment there were 2 groups of rats consuming the same total amount of food daily (about 7 gm.) but one received twice the amount, and the other one-tenth the quantity, of B vitamins considered optimal. The mortality in these two groups following infection with typhus is shown in Table 4. As can be seen, 9 of the 11 rats on the diet containing one-tenth the quantity of B vitamins succumbed on

TABLE 4

Results Following Infection in Rats Subjected to Diets Differing in Quantity of Vitamins of B Group

† One rat dead of intercurrent infection before inoculation.

the 5th, 6th, and 7th days. Three of those on a double portion of vitamins died, but death was delayed. This experiment would lead one to conclude that curtailment of the B group of vitamins renders rats much more susceptible to infection with typhus. As a check, we are carrying out feeding experiments in which adequate vitamins are given separately while the quantity of protein is varied.

2. *Individual Vitamins of B Group*—Our next object was to determine which of the vitamins in the B-complex was important to resistance. In these experiments all rats were fed the complete diet *ad lib.* exclusive of the B group of vitamins. The latter were fed separately each day in castor cups to insure their consumption. Table 5 shows the quan-

toms. It was found that no increased susceptibility resulted when choline, nicotinic acid, pyridoxine, or para aminobenzoic acid were reduced to one-twentieth optimal levels, but that reducing pantothenic acid, riboflavin, or thiamin to this level resulted in mortality which was greater than that of controls. It was surprising to find that 3 vitamins could have this effect. In order to bring out the relative importance of these 3 vitamins and to make the results clear cut, they were reduced to one-fortieth the optimal level and tested simultaneously. The results of such an experiment are shown in Table 6. Deaths occurred first among pantothenic acid and thiamin deficient rats and were delayed in the riboflavin deficient group. It remains to be shown whether a deficiency of all 3 of these vitamins in the same group of rats results in greater susceptibility than the single deficiencies. Pyridoxine, choline, or nicotinic acid reduced to one-fortieth the optimal level were without effect. The result of inositol deficiency is still to be investigated, though since it is not essential for the rat, susceptibility probably will not be increased. Obviously, the therapeutic effectiveness of pantothenic acid, riboflavin, and thiamin must be tested in infected rats.

It was noted that the response to infection of rats on the deficient diets frequently was not typical. As was observed by Zinsser and coworkers,¹ the deficient animals usually had no rise in

TABLE 5

Quantities of Vitamins of B Group Given Daily to Rats on Normal Diet

| Vitamin | Gamma/Day |
|------------------------------|-----------|
| Thiamin | 80 |
| Pantothenic Acid | 440 |
| Pyridoxine | 80 |
| Para aminobenzoic acid | 400 |
| Niacin | 400 |
| Riboflavin | 160 |
| Inositol | 2,160 |

tities of vitamins fed to control rats. To determine the effect of deficiencies of vitamins of this group, one member at a time was reduced to one-twentieth the optimal level. This was a purely arbitrary restriction which resulted in an impaired gain in weight in some experiments without producing, in most instances, any striking deficiency symp-

TABLE 6

Results Following Infection in Rats Subjected to Diets Low in Individual Vitamins of B Group

temperature. We found, in addition, that there was seldom any enlargement of the spleen or scrotal swelling.

Other experiments involving less specific factors have also been done, such as the addition of liver to the complete synthetic diet, and the comparison of the natural with the synthetic diet. The inclusion of 1 per cent liver powder in the complete synthetic diet did not increase the resistance of the animals to typhus.

3. *Natural and Synthetic Diets*—In preliminary tests of infectious yolk sac material, it was observed that when rats on a natural diet were used they sometimes withstood doses that proved fatal to animals on the complete synthetic diet. This was surprising in view of the fact that the latter diet contained all known factors in optimal quantities. To test the validity of this observation, 26 weanling rats were placed on the natural diet for a period of 2 weeks, at the end of which time 12 of the 26 were put on the complete synthetic ration, the rest being kept on the natural diet. After a further period of 4 weeks both groups were infected. The rats on the synthetic diet weighed on the average 14 gm. more than those on the natural diet. About 3 days following infection, the animals on the synthetic diet exhibited the listlessness, irritability, anorexia, and loss of weight typical of a severe typhus infection in the rat, and 2 of the 12 died. The appearance of the animals on the natural diet was in striking contrast. They were alert; they ate well; and there were no deaths. One can perhaps postulate that there is an unrecognized food factor supplied by the natural diet, or that the cruder diet promotes the synthesis of some unknown factor by the bacterial flora of the intestine which increases resistance.

DISCUSSION

Some explanation for the observed connection between typhus and famine

has been arrived at in the foregoing experiments, if the results obtained with rats can be applied to man. At the start of the work it appeared that a diet low in protein and a diet low in vitamins of the B group each increased susceptibility. By means of paired feeding experiments it was shown that the vitamins were the important factor. The increased susceptibility of rats on a low protein diet can be explained by the fact that they ate very little and, therefore, did not get their daily vitamin requirement. This condition without doubt has its parallel in devastated countries where populations subsist on monotonous and inadequate diets which act as deterrents to appetite. Of the 3 vitamins which specifically increase the susceptibility of the rat to typhus, thiamin is known to be a great stimulant to appetite. If it should be lacking in the human diet, inadequate consumption of riboflavin and pantothenic acid might follow. It is interesting to note that the same foods are often the best sources of these 3 vitamins, and they are foods which are seldom available to the victims of war and poverty.

SUMMARY

1. The susceptibility of rats to typhus was increased by the following types of deficient diet: (1) low protein, whether containing adequate amounts of vitamins of the B group or not; (2) a diet normal in protein, containing one-tenth the quantity of vitamins of the B group considered optimal; (3) a diet complete except for reduced pantothenic acid; (4) a diet complete except for reduced riboflavin; (5) a diet complete except for reduced thiamin.

2. Rats on a natural laboratory diet were less susceptible than those fed a complete synthetic diet.

3. No increased susceptibility was observed when pyridoxine, nicotinic acid, choline, or para aminobenzoic acid were reduced in otherwise complete diets.

4. The addition of 1 per cent liver powder to the complete synthetic diet did not increase the resistance of the rats to typhus.

NOTE: The suggestions of Dr. J. H. Jones relating to the composition of the basic rat diet are gratefully acknowledged.

Specialty Board in Preventive Medicine

On February 3, a forward step toward professional recognition of preventive medicine as a distinct medical specialty was made by the formation of an "Interim Board" of Preventive Medicine in the Army, Navy, and Public Health Service, according to an announcement made jointly by the Surgeons General of the three Services.

Six civilian authorities and one representative each of the three services were designated to form the Interim Board. The six civilian representatives are: Dr. Gaylord W. Anderson, Director, University of Minnesota School of Public Health; Dr. Thomas Francis, Jr., Professor of Epidemiology, University of Michigan School of Public Health; Dr. Wilton L. Halverson, California State Director of Public Health; Dr. Harry S. Mustard, New York City Health Commissioner; Dr. Hugo Muench, Assistant Dean, Harvard School of Public Health; Dr. Ernest L. Stebbins, Director, Johns Hopkins University School of Hygiene and Public Health. Chiefs of the Preventive Medicine Divisions of the Army and Navy, and an officer selected by the Surgeon General of the Public Health Service, complete the roster. These are: Captain Otto L. Burton, U. S. Navy; Dr. James Crabtree, U. S. Public Health Service; and Colonel Tom F. Wayne, U. S. Army. Dr. Ernest L. Stebbins was elected Chairman of the Board which began drafting a preliminary

bill of requirements for certification.

The Interim Board was formed chiefly for the purpose of setting up certification requirements for medical officers in the three services seeking to qualify as specialists in preventive medicine. This coöperative effort of the services will, however, also give considerable impetus to a demand for creation of an American Board of Preventive Medicine and Public Health, to take its place along with the 16 medical specialty boards already in existence. The three Services have expressed their intent to discontinue the Interim Specialty Board as soon as a civilian specialty board is established.

The Committee on Professional Education of the American Public Health Association and the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association have recommended that an Organizing Committee for an American Board of Physicians in Preventive Medicine and Public Health be established, consisting of members representing the American Medical Association, the American Public Health Association, the Canadian Public Health Association, the Association of Schools of Public Health, and the Southern Medical Association. Representatives from these organizations have recently been appointed. Further progress will be reported to our *Journal* readers as new developments take place.

The Epidemiology of Rheumatic Fever; Its Public Health Aspects*

GEORGE C. GRIFFITH, M.D., F.A.C.P.

*Clinical Professor of Medicine, Director, Graduate Division, School of Medicine,
University of Southern California, Los Angeles, Calif.*

NEXT to tuberculosis and syphilis, rheumatic fever, a post-streptococcal syndrome, is our third most common infectious disease. Little has been done in the promotion of public health measures to control this disease, for several obvious reasons. These are three in number; first, the etiology of rheumatic fever has not been clearly understood, in spite of the fairly well known fact that rheumatic fever and the hemolytic streptococcus infections are related; second, there is no specific diagnostic test for rheumatic fever comparable to the tuberculin test for tuberculosis or the Wassermann test for syphilis; and, third, there has been no general acceptance of any standard program of preventive measures.

The understanding of the epidemiology of rheumatic fever is important because it is the foremost cause of death in individuals under the age of 20 years. Infantile paralysis, while more dramatic in its onset and far more widely publicized, causes less than one-tenth as many deaths annually. The subject of the epidemiology of rheumatic fever has been well covered by Paul's monograph published in 1943, and more recent statistical studies have confirmed his findings, with additional emphasis on the wide distribution of the disease. Studies made upon young men who were rejected for military service because of

cardiac disease during 1942 and 1943 revealed rheumatic valvular heart disease as comprising 51 per cent of the total number in Boston, 70.3 per cent in Chicago, 64.4 per cent in New York, 65.9 per cent in Philadelphia, and 39.6 per cent in San Francisco. Armstrong and Wheatley¹ offered evidence of "hereditary" susceptibility to rheumatic fever which is said to indicate a Mendelian recessive character. It is not clear how much susceptibility may be due to the state of nutrition and environment shared by family groups rather than to heredity.

The close relationship between hemolytic streptococcus infection and the rheumatic state has been demonstrated by a number of observations. These have been carefully evaluated by Rautz and his associates.⁷ Rheumatic fever follows known hemolytic streptococcus infection, especially when involving the upper respiratory tract. Epidemics of rheumatic fever have often succeeded outbreaks of scarlet fever and other forms of streptococcal sore throat. Reactivation of the rheumatic state frequently develops when a new infection by the hemolytic streptococcus occurs in individuals who have had rheumatic fever previously. High titers of various anti-streptococcal antibodies and cutaneous hypersensitivity to products of hemolytic streptococci are usually demonstrable by immunological means in those suffering from active rheumatic fever. In the rheumatic fever studies among military personnel, it was noted that the most

* Read before the Public Health Section, California State Medical Association, Los Angeles, Calif., May 2, 1947.

constant epidemiological finding was exposure to hemolytic streptococci.

In the past it has been accepted that rheumatic fever is a disease of the temperate zone. Investigations in more tropical regions have thrown doubt on this conclusion. Suarez reported that rheumatic heart disease in Puerto Rico amounted to 20 per cent of all cardiovascular disorders. Sampson, *et al.*⁹ found rheumatic fever in the warm, dry sections of California in a degree comparable to cities with temperate climates, such as Cincinnati and San Francisco. Medical officers report the frequency of active rheumatic fever in the New Hebrides and in the Samoan Islands. Climate does not appear to be a large factor in the epidemiology of rheumatic fever. In military installations it was apparent that two circumstances were prominent in the rapid spread of hemolytic streptococcal disease; one, the concentration of large numbers of people within relatively small areas; the other, the constant introduction of new members to the group. Since military installations, especially training stations, are necessarily subjected to these two circumstances, they become ideal soil for epidemics. Clinical observers have found that they are able to predict with fair accuracy the number of cases of rheumatic fever which can be expected to develop after an outbreak of scarlet fever or of tonsillitis in a training camp. Five to 10 per cent of these patients developed recognizable rheumatic fever in such camps.

Factors commonly held responsible for their part in the epidemiology of rheumatic fever, such as climate, precipitation, marked variations in temperature, and familial susceptibility, may be significant only because under these conditions there is likely to be crowding in a limited space, lack of sunlight, and limitation of diet which may create the soil for epidemic streptococcal throat infections.

Undoubtedly a great many cases of streptococcal throat infections are overlooked. A mild streptococcic pharyngitis may be dismissed lightly after a few days, even if it has come to the attention of a physician. This is particularly true in the milder climates where more severe manifestations of the streptococcic throat infections and even those of rheumatic fever may be minimal or absent. An active rheumatic state is frequently found without any joint manifestations. This is common in the warmer climates, but may occur anywhere; and the lack of characteristic arthropathy allows much severe cardiac damage to develop unnoticed. More important than this, rheumatic fever is not classed as a reportable disease in many states. This tends to keep the medical profession in ignorance of its existence in such areas.

Wheatley¹ calls attention to the seasonal incidence which has always been noted as a striking characteristic of rheumatic fever. April is the high month, with September and October the low months. This may be regarded as another aspect of a disease whose cause is dependent upon respiratory infections, and which follows the peak of the streptococcal curve by several weeks. This pattern has been altered where military installations provide the crowding and high turnover which give rise to outbreaks of streptococcal infections regardless of seasons. Therefore, it may be stated that where conditions are conducive to hemolytic streptococcal epidemics, rheumatic fever in epidemic form will follow. The epidemiology of rheumatic fever is essentially the same as that of hemolytic streptococcal throat infections.

In a review of the histories of 1,046 rheumatic fever cases which developed during military service, several facts became clear. First, the state from which the youth came was of less importance than the incidence of respiratory infections in the training camp to which he

was sent; second, youths from the urban districts were slightly more prone to develop rheumatic fever than were trainees from the rural sections; third, tonsillectomy performed prior to military service did not materially protect the individual from developing the disease. These facts tend to reinforce Paul's belief that rheumatic fever is a "crowd disease." Paul pointed out that rheumatic fever is more prevalent in urban than it is in rural children, more frequent in river-side damp and wet homes, and occurs oftener in dwellings where crowding, poor ventilation, uncleanness, and poor nutrition are found.

Much has been written about the type of individual who develops rheumatic fever. The observers of over 10,000 rheumatic fever patients in one Naval installation were unable to find any one type which predominated. The dark complexioned, swarthy individual developed the disease as frequently as did the often described red or auburn-haired, freckle-faced, thin individual. No particular stock was found to be more susceptible. The Negro race, however, differs in that there is an increased vulnerability to the ravages of rheumatic fever after it has been acquired, rather than a greater tendency to develop the disease.

A hereditary susceptibility to rheumatic fever has been believed to determine the incidence of rheumatic fever. This view, beginning with Cheadle³ 46 years ago and supported by considerable new work by Wilson and Schweitzer,¹⁰⁻¹¹ has been attributed to a single autosomal recessive gene which, when distributed among the population, has made the bearer susceptible to the disease. It is true, as shown by many workers—most recently by Gould and Read—that children of rheumatic parents have higher attack rates than do the children of non-rheumatic parents. The problem of hereditary susceptibility finally comes down to an analysis of

family incidence. In a very carefully controlled study, the writer¹² and his associates interviewed 3,594 rheumatic fever patients and 1,397 non-rheumatic patients in an attempt to answer this question. An opportunity presented itself to study this large number of patients from the standpoint of the familial relationship in those individuals who developed rheumatic fever before separation from the family and in those who developed the disease after separation from the family unit. The total number of individuals studied was 4,991. Table 1 shows the number of individuals in each of the following groups.

TABLE 1

Number of Patients Studied in the Various Groups

| Group | Number |
|--|--------|
| Developed rheumatic fever after leaving home | 3,611 |
| Did not develop rheumatic fever after leaving home | |
| Tuberculous cases at Corona Naval Hospital | 519 |
| Medical and surgical patients at Birmingham General Hospital | 607 |
| Intern and resident physicians at a civilian hospital | 254 |

The question arose as to whether these individuals were likely to have been equally well informed concerning the occurrence of rheumatic fever in members of their families. It was suspected that individuals who had not had the disease at any time might be relatively uninformed in this respect by comparison with those who had developed the disease, unless the individual was himself a physician. On review of the data this was found to be the case; among those who had not themselves had the disease, non-medical individuals reported a significantly lower familial incidence than did physicians. It was, therefore, necessary to exclude from this analysis of the effects of familial rheumatic fever all of those individuals who had not had the disease themselves and were not themselves physicians, the number of cases so excluded on the basis of inadequate information being 1,082.

With respect to the influence of one attack of the disease upon the development of later attacks after leaving home, however, there was no reason to suppose the knowledge of an earlier attack to have been inadequate in those failing to develop a later attack or particularly sufficient in those who did; all 4,991 cases were therefore used in this analysis.

In the "informed groups," as defined above, a study was made of the relationship between a positive family history of rheumatic fever and personal development of the disease while still in contact with the family. The results, in the form of a contingency table, are shown in Table 2.

TABLE 2

Relationship between Family History and Personal Attack before Leaving Family

| Family history | Personal History Before Separation from Family | |
|----------------|--|----------|
| | Positive | Negative |
| Positive | 369 | 258 |
| Negative | 551 | 2731 |

It is seen that these results could not possibly have been due solely to chance, and that there is a definite tendency for the individual with a positive family history to have the disease while still in contact with his family.

A study was next made of the relationship between a positive family history and the personal development of the disease in the individual after separation from his family. The results, in the form of a contingency table, are shown in Table 3.

TABLE 3

Relationship between Family History and Personal Attack after Leaving Family

| Family history | Personal History After Separation from Family | |
|----------------|---|----------|
| | Positive | Negative |
| Positive | 582 | 45 |
| Negative | 3,029 | 253 |

It is noted that these results could easily have been due solely to chance, and that there is, therefore, no relationship between family history and the

personal development of the disease after separation from the family. This same conclusion is reached when the cases are separately studied according to their own past personal histories.

From Tables 2 and 3 it is concluded that a positive family history is important only so long as the individual remains in contact with the family, and that the positive family history has no influence upon the subsequent development of the disease. It is, therefore, possible to study the role of a past personal history upon the risk of developing rheumatic fever without regard to family history. The reason for excluding the relatively "uninformed group" from such a study is now no longer present, since they are presumed to be uninformed only in respect to the family history.

Table 4, therefore, shows for all individuals the relationship between personal past history of rheumatic fever and the later development of the disease.

TABLE 4

Relationship between Personal Past History of Rheumatic Fever and the Later Development of the Disease

| Past History of Rheumatic Fever | Later Development of Rheumatic Fever | |
|---------------------------------|--------------------------------------|-------|
| | Yes | No |
| Positive | 861 | 59 |
| Negative | 2,750 | 1,321 |

This result could not have been due solely to chance, and it is, therefore, clear that a positive personal history does tend to influence the patient to the later development of the disease. It is obvious, therefore, first, that an attack of rheumatic fever earlier in life tends to facilitate a later attack, but that this difference is not great; and, second, that the occurrence of rheumatic fever in the family increases the risk of the individual developing the disease while still in contact with the family, but not after he is separated from the family. There does not, therefore, appear to be a strong and inherited susceptibility. The oc-

currence of multiple family cases could be explained either on the basis of common environment or contagion.

Therefore, it would seem fair to conclude that the high prevalence of rheumatic fever is not hereditary, but domiciliary. Environmental factors in the home play a large part in timing the onset of rheumatic fever after family epidemics of streptococcal infections such as scarlet fever. From the standpoint of epidemiology, rheumatic fever is a crowd disease following closely upon *Streptococcus hemolyticus* infection. The higher incidence in the poorer homes, in cities and in cold, damp climates is due to contact with the hemolytic streptococcus. The epidemiology of rheumatic fever thus becomes analogous to the epidemiology of tuberculosis.

It is clear that to eliminate rheumatic fever and related disorders associated with the post-streptococcal state, a complete suppression of infection in human beings by the hemolytic streptococcus is necessary. Rautz⁷ stressed this point in a paper read before this Section 2 years ago. The overwhelming magnitude of the problem needs to be emphasized to create sufficient interest in professional and lay groups. When it is realized that rheumatic fever and valvular heart disease are the most frequent cause of death between the ages of 5 and 24 years, then an approach to this problem will be made comparable to the successful control of tuberculosis.

The first public health measure to be taken is education. Physicians and associated professional personnel must be informed of the fact that every patient with a hemolytic streptococcal throat infection is a potential rheumatic fever subject. Perhaps it would be wise not to use the term rheumatic fever and to talk about the post-streptococcal state. Physicians, nurses, teachers, and parents should know this fact and be alert to find the child who is pale, nervous, and easily fatigued; and in the presence of

these symptoms to suspect the rheumatic state.

The second public health measure is that of case finding. California is the 46th state in the number of cases of rheumatic fever reported; yet it is the 18th in the number of rheumatic fever and rheumatic heart disease deaths. The frequency of the rheumatic state is comparable in this climate to that of other cities, such as Cincinnati, as shown by the studies of Sampson and his associates,⁹ as well as by studies now in progress by the author. Again it must be emphasized that case finding will depend largely upon the education of physicians, nurses, and teachers, as well as parents. Local facilities for the specialized study of suspected cases should be set up. In Pasadena, Calif., alert pediatricians, a wide awake school physician and an intelligent heart committee of the Tuberculosis and Health Association have joined in a program of case finding, and a diagnostic clinic with follow-up care.

The third and probably the most difficult public health measure is the control of streptococcus epidemics. Isolation of all cases with positive streptococcal throat cultures has been effective in limiting epidemics in military installations. Most public health departments require the isolation of the scarlet fever patient, yet do not isolate patients who do not develop a rash. Also, since it is known that virulent hemolytic streptococci exist in the nasopharynx for many weeks after the acute manifestations are past, and that many healthy carriers harbor the same virulent streptococci, the desirability of isolating all patients with suspected streptococcal infections in the hope of preventing the spread of the disease can be realized.

The control of healthy streptococcus carriers becomes most difficult, since at varying seasons of the year from 5 to 50 per cent of the population may harbor these organisms in the nasopharynx. So

like histologic lesions by sensitization with sulfonilamide. Especially is this true, considered in the light of the Army Air Force experience, where frequent reactions to the sulfonilamides were caused by repeated administration of the drug when given in prophylactic dosage to the Army Air Force personnel. Toxic reactions are few if the drug is withdrawn when the early symptoms of hypersensitivity appear. Severe reactions occur if the drug is administered repeatedly to sensitized individuals. Therefore, in every epidemic the streptococcus should be tested *in vitro* to find out if the epidemic strain is definitely inhibited by low concentrations of the drug. It is of more importance that the drug should be withheld from all persons who are sensitive to sulfonilamide, and that all persons receiving the drug be readily available for frequent examinations by the physician.

Biologic prophylaxis with the use of sera and vaccines has so far proved unsatisfactory. Immunity is type-specific, and polyvalent vaccines are required. The real danger in inoculation of human beings by these organisms is the production of streptococcal tissue hypersensitivity, which may increase the possibility of causing post-streptococcal complications such as rheumatic fever, if and when suppurative streptococcal invasion of the throat occurs.

Antibiotic prophylaxis is expensive and, as yet, impractical. Penicillin therapy at the time of the invasion of the tissues of the throat shortens the illness and has proved to be the best preventive of the post-streptococcal complications and of the reactivation of quiescent rheumatic fever.

If a substance which acts like the salicylates, in a very effective way, can be found, then the sensitizing reaction will be blocked. The hope of investi-

gators working at the present time, is to find a substance which will prevent the antigen of the streptococcus from sensitizing the host, and thus block or prevent the post-streptococcal state.

SUMMARY

1. The epidemiology of rheumatic fever is the epidemiology of the Group A hemolytic streptococcus.
2. Respiratory disease caused by the hemolytic streptococcus predisposes to the post-streptococcal non-suppurative complications.
3. Rheumatic fever is a contact disease, and not primarily due to an inherited susceptibility to the disease.
4. The public health measures for the control of rheumatic fever are similar to those instituted so successfully in the control of tuberculosis.
5. Isolation, control of carriers, air sterilization, and possibly chemoprophylaxis are measures necessary for the prevention of epidemics.
6. The chief problem is the protection against, or the elimination of, infection by streptococci from the whole population.
7. A blocking agent, to prevent the development of the post-streptococcal syndrome, i.e., rheumatic fever, is a logical attack upon the problem.
8. The solution of these problems is the first step in the prevention of rheumatic heart disease, and perhaps in the prevention of the wide-spread vascular diseases, as well.

General Reactions of Mothers and Nurses to Rooming-in

Observations Based on Experience in a Four Bed Rooming-in Unit in the Grace-New Haven Community Hospital (University Service) *

EDITH B. JACKSON, M.D.

Associate Clinical Professor of Pediatrics (Psychiatry) Yale University School of Medicine; Attending Pediatrician, University Service of Grace-New Haven Community Hospital, New Haven, Conn.

ROOMING-IN is the term used for the hospital arrangement whereby a mother may have her baby in a crib beside her bed. This paper summarizes the general reactions of mothers and nurses to rooming-in as carried on during the past 11 months on the maternity ward of the Grace-New Haven Hospital in the so-called Rooming-in Unit. The Unit is housed in the maternity ward solarium which has been partitioned off into a four bed, semi-private ward with attached four cubicle nursery and doctors' and nurses' office. The baby's crib is usually by the mother's bedside but may be moved to the nursery at the end of the room as occasion arises. The upper part of each partition is glass with draw curtains, so that there may be visibility or seclusion as desired. The partitions stop three feet short of the ceiling for ventilation purposes. The ceiling and side walls of the nursery are treated with acoustic-celotex to reduce the intensity of sounds and noises. The room is cheery and attractive. The Rooming-in Unit is thus a comfortable division of hospital space wherein four mothers and their new-born babies may be cared for together under unified nursing and medical supervision, and where

each mother may observe her baby to her heart's content and learn to take care of him before she leaves the hospital.

As hospitalization for maternity cases has increased during the last 25 years, many mothers have felt the lack of opportunity to get acquainted with their babies during the lying-in period. They have subsequently admitted feeling panicky and helpless in dealing with the baby immediately after coming home from the hospital. During this same period, some physicians who have had the opportunity to study feeding problems and other behavior disturbances of infants and young children, together with the neuro-psychiatric disturbances of adults, have expressed the opinion that the separate care of maternity and new-born patients in the hospital and the extension of the hospital's rigid schedule into the home has offered a favorable medium for the growth of unnecessary conflict between mother and child. Furthermore, mothers from all sections of the country who have wanted to nurse their babies as a natural maternal process have felt thwarted by the disinterested attitude of the hospital medical and nursing staffs in supporting their wish to nurse. They have felt both puzzled and hurt by their failure to provide what they had reason to ex-

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

sider was the best food for their infants. Some physicians (pediatricians, psychiatrists, and obstetricians) listening to such comments and complaints from intelligent parents, have gained a conviction that the hospital's institutional need for regularity and regime has blocked a recognition of the mutual needs of mothers and new-born babies within the hospital.

Since the major part of the education of physicians and nurses is in hospitals, and since approximately 80 per cent of the babies born throughout the United States and 90 per cent of the city born babies are at present delivered in hospitals,¹ hospital practices have very far-reaching effects, and also very profound effects, for they bear the stamp of the acme of medical authority. Physicians, nurses, and parents educated in the hospital to a firm belief, both in the nursery segregation of new-born infants and in strict routine and regularity as a correct procedure for infant care, have had little reason to question either until practical experience or further education or both has taught and convinced them otherwise. There are now throughout the country parents, physicians, and nurses who singly or in groups are expressing other convictions.²⁻⁷ Good hospitals, they are saying, have certain advantages over homes for safety in maternal and new-born care; good homes have certain advantages over hospitals in naturalness and comfort. Protection from infection and protection from discomfort may be equally essential for the baby's happy, healthy development and for the mother's ability to give adequate care to her child. Cannot the advantages of safety and home-like comfort be combined in the hospital for the welfare of normal healthy mothers and infants, and for the more realistic education of parents, physicians, and nurses in the interrelationship of maternal and infant needs?

The Rooming-in Unit on the Univer-

sity Service of the Grace-New Haven Community Hospital is the joint cooperative attempt of the Department of Pediatrics and the Department of Obstetrics and Gynecology of the Yale University School of Medicine, of the Yale School of Nursing, and of the Hospital Administration to answer that question.

REACTIONS OF MOTHERS

In discussing the reactions of mothers we will consider first the reactions of prospective mothers to the idea of rooming-in. During the first 3 months of our work the existence of the Unit was not generally known. We could, therefore, question the expectant mothers in Prenatal Clinic with reasonable assurance of a spontaneous response from them, unbiased by previous hearsay or consideration. Our initial phrasing of the question was as follows:

In our experience we have found that some women think that they might prefer to have the baby in the room with them in the hospital. Other women would rather have their babies in the nursery and brought to them at regular feeding hours. Which would you prefer?

This question was asked only of the mothers who in a preliminary or screening interview had signified their wish to breast feed, since we were studying rooming-in with special reference to the type of woman who wanted help and encouragement from the hospital in undertaking to breast feed her baby. There were many immediate smiling responses to the suggested idea of having the baby close to the mother's bed; there were some incredulous, hesitant, dubious responses, and a few immediate negative responses. Table 1 figures from the first 8 months indicate, however, that of the mothers who looked forward to nursing the baby, more favored the idea of rooming-in than disapproved of it.

As a further check on the reaction of expectant mothers to the idea of room-

ing-in during the last 3 months (from July 1 to September 30, 1947) every mother interviewed in the Prenatal Clinic by a member of the Rooming-in staff has been asked whether she would like to have her baby beside her bed if it were possible. Table 2 figures indicate that more than half of the expectant mothers (whether they wanted to breast feed or bottle feed their babies) are positively in favor of the idea, that a quarter of the mothers are definitely opposed, and the remaining one-fifth of the total group are indifferent.

TABLE 2

| <i>Attitude of Expectant Mother</i> | <i>Number</i> | <i>Per cent</i> |
|---|---------------|-----------------|
| Favorable | 184 | 55.0 |
| Unfavorable | 88 | 26.5 |
| Indifferent | 59 | 18.5 |
| | 331 | 100.0 |

This test of attitude toward rooming-in of all expectant mothers in the Prenatal Clinic was undertaken merely as a poll of opinion because of the increase in the number of spontaneous requests for rooming-in both from clinic and private patients. However, mothers continue to be selected on the original basis of (1) wanting to nurse; (2) wanting rooming-in; and (3) relative normality. Parity, age, race, economic or social status have not, *per se*, been determinants in selection; in these respects selection has been representative. The weighting of the selection in terms of the expectant mother's wish to nurse her baby has probably brought to rooming-in a relatively high proportion of well educated parents. In this connection it is a noteworthy fact that married nurses and wives of graduate students, of medical students, and of medical staff, have

been eager applicants for rooming-in and enthusiastic participants.

The first indications of satisfaction on the part of both mothers and nurses to rooming-in experience appeared promptly. The first group of student nurses assigned to the Rooming-in Unit made a special point of expressing their viewpoint in the following way at the end of their two week assignment:

"We know the mothers like rooming-in. We thought you would like to know the nurses like it, too, and when we have babies this is the way we would like to have them." The spokesman of this group married a few weeks later. She documented the sincerity of her response by applying for rooming-in shortly after she knew she was pregnant.

Some might comment that the first mothers to be cared for in the Rooming-in Unit would of course be pleased and satisfied; they wanted to come, in the first place, and the care and the attention would be particularly attentive under the stimulus of the newness of the venture. However, the enthusiastic response of the mothers has continued month after month. After all, for each successive group of mothers and each successive group of student nurses in the Unit there is the same stimulus of a new and vital experience. During the first 3 months most of the mothers wrote comments in notebooks that were provided for the record of their care of the baby. These comments were all on the appreciative side. We had every reason to believe in their sincerity, since very often practical suggestions were added. For instance, one of the first primiparous mothers called our attention to the fact that it might be better to assume that the baby should spend the first couple of nights in the little nursery at the end of the Unit, and not put the burden of decision on the mother. No mother, she said, would want anybody to think she did not want her baby, even though at the moment she wanted undisturbed

quiet most of all. Other mothers made other suggestions. It was evident that they enjoyed participation in an undertaking that was trying to make the mutual adjustment of mother and new-born a happy experience, for themselves and for their successors.

The same reasons for liking rooming-in appeared over and over again in the comments from different mothers, whether primipara or multipara. They liked to watch the baby, his facial expression, his smiles, his movements. They liked to hear his baby sounds. They did not worry what was happening to him as all multiparous mothers said they did when their former babies were in the ward nursery. They felt secure in having the same nurse take care of the baby who was taking care of them. They liked being able to ask either nurse or doctor questions as soon as questions arose. They learned much in the care of the baby by watching the nurse during the first few days, and gained assurance in taking care of the baby themselves under supervision during the last few days of the hospital period. For the most part, they liked the *ad lib* schedule, because they could observe the easy contentment of the baby. They greatly enjoyed the father's visits, and his participation in holding and learning to care for the baby.

The following appreciative comment on rooming-in, recently received from a mother with her first baby, is typical.

What do I think of Rooming-in? I think it is wonderful. There are a great many observations I could make—all of them complimentary. However, in that case this would become a thesis rather than merely a "list of comments," so I shall simply mention the two most important factors in my impression of this experiment.

My baby girl, Diane Margaret, and I will be going home tomorrow, and I know that if I had not been given the privilege of being in Rooming-in, I would be a nervous wreck tonight. I have often heard the adage that a new mother invariably cries the night before she goes home from the hospital. Well, I can

easily see why. Even though she has read literature on baby care and perhaps attended Mothers' Classes, still she has had no experience in caring for a real live baby. Here in Rooming-in, we new mothers learn first by watching the nurses care for our babies, and then we augment that knowledge with actual experience. Also, we are given answers to all the many important and perhaps some trivial questions that come into our minds as we watch that wonderful little son or daughter.

Our course in Mothers' Classes gave us a great many helpful hints on breast feeding, but in Rooming-in, through the untiring efforts of the nurses and doctors in charge, a mother's desire to nurse her baby finds fulfillment. This is the most important reason why I hope there will be many Rooming-in Units in the new hospital. There are many girls today who sincerely want to breast feed their babies, but they are never given the right start in the hospital, and they find themselves going home with a bottle-fed baby. This situation is a disgrace.

Another great advantage of Rooming-in is that the previously neglected father, who could only see his baby through a glass window, now is given his rightful privilege. He now can watch his baby, hold her, learn to care for her. Consequently, when mother and baby come home, he does not feel afraid or self-conscious, and can be a real help and comfort.

The multiparous mothers, without exception, expressed preference for the rooming-in experience over their previous hospital experience, and stated that they got as much if not more rest in rooming-in as they had had previously; in any event, they said, they felt stronger and more rested at the end of their hospital stay and much more ready to undertake the care of the baby at home. Furthermore, they expressed appreciation for the companionship with other mothers which the Unit afforded. They learned much by observing the other mothers with their babies and exchanging experiences. They became used to the idea that each baby was quite different from every other baby, and that each baby differed in reactions from day to day. They felt they were going home with a baby they really knew, and not with a perfect stranger. Many commented after they had gone

each nurse is able to take care of several mothers and babies throughout the lying-in period and conversely that the mothers have the same set of nurses caring for them throughout their hospital stay. This has been a satisfactory and instructive arrangement for both mothers and nurses. In the first 10 months of operation of the Unit there have been approximately 60 student nurses who have had this experience. Each student has written an evaluation of her obstetrical experience contrasting the experience in the Rooming-in Unit with that on the usual obstetrical ward and nursery service. The obstetrical supervisor⁸ has stated:

Without exception every single student who has been assigned to the Rooming-in Unit has been most enthusiastic about her experience there. Their comments were all in favor of the arrangement. The students say over and over again that this is the first time in their nursing education experience that they have been able to give what they consider ideal care to a patient. I am convinced that this bit of experience, although at the present only 2 weeks in length, is of unexcelled value to the student. She is able to observe every single thing that happens to the mother and the baby and the mother and baby together. She has an opportunity to teach the parents about their new baby. She has an opportunity to explain to them or to answer for them many of the questions that come up in this new relationship. . . . I believe that the nurse giving this care will herself be better prepared both as nurse and as potential mother.

One student writes in contrasting her maternity ward and new-born nursery experience with her rooming-in experience: "It was a sort of race with time that left no individuality for anyone. There wasn't time to wait and see if the baby had taken the breast nor was there time to stop and encourage the mother with the poor nurser, but rather some impatience with the mother who wanted to finish combing her hair or fixing her face at 6:00 a.m. rather than taking the baby. Rooming-in was a great change from the aforementioned. Although we were kept busy, we were not rushed, and there was plenty to do. Having the mother with the baby seemed to make the mother more considerate of the nurse's time. She didn't ask for things to be

done when she could see that the nurse was busy with another mother and baby."

Another writes: "There is a relaxed, peaceful attitude about the Unit which runs without the everlasting clock-control that is found in larger units and especially in the nursery. I did not like working in the nursery or on the ward. In the nursery I felt as though I were running a machine which had to produce freshly diapered babies with a heated formula every 4 hours, and I did not like it on the ward because I felt intensely rushed with beds, baths, meals, and routine postpartum care."

The Visiting Nurse Association of New Haven is represented on the Rooming-in Committee. A cordial working relationship is maintained between the Rooming-in staff pediatricians and the visiting nurses who visit in the homes of rooming-in families through exchange of telephonic reports. As previously indicated, some of the visiting nurses have reported finding rooming-in mothers more independent than other mothers just home from the hospital and more quick to dispense with their practical help. Some of the visiting nurses have found, on the other hand, more time being claimed by rooming-in mothers who want to talk out with the nurse a somewhat complicated family or economic problem in relation to the baby's welfare. Reports on the babies have been generally favorable.

CONCLUSIONS

Procedures in the Rooming-in Unit have met with generally favorable response from both mothers and nurses (and also from staff physicians, fathers, and infants). It has proved to be a helpful educational experience for everyone involved. Multiparous mothers prefer it to the usual hospital procedure because of the help it offers them in getting a good start with the baby, and they therefore recommend it for mothers of first babies. It is too early to evaluate any long range effects. Rooming-in is not applicable to all mothers, and

new methods, new techniques and new standards. Personnel of this type can be obtained only by making special training available to qualified candidates, by financing postgraduate study in public health and by offering scholarships to promising students who are eager to make public health work a career.

The need for capable physicians and nurses, for sanitary engineers, bacteriologists, epidemiologists, statisticians, public health educators, and technicians is a need which has seriously limited the operation of official agencies. Through a series of direct grants to the U. S. Public Health Service and professional organizations, the National Foundation is financing the development of personnel to fill these essential positions. Fully realizing that the conquest of poliomyelitis hinges upon the intensity of the fight against all diseases, we are today strengthening the position of officially constituted organizations by contributing thousands of dollars to the training of public health workers. Let me tell you some of the things that are being done in this respect.

Early in 1946 there existed 1,200 vacancies for physicians and engineers in state and local health departments throughout the country. In a move to encourage widespread interest in public health on the part of physicians and engineers returning from military service, the U. S. Public Health Service applied to the National Foundation for funds to be used in the public health training of personnel recruited to fill these positions. The application was approved in July of last year and a grant of \$228,400 made to provide fellowships for qualified candidates. Up to September 30 of this year 35 awards have been made to sanitary engineers and 18 to public health physicians. Additional applications are under consideration. We feel that the presence in health departments of well trained health officers

and sanitary engineers assures us of maximum efficiency in our efforts to control poliomyelitis. And our support of official agencies does not stop here.

Health education through the facilities of the U. S. Public Health Service has long been hindered by the lack of trained personnel. The well trained health educator, working as a permanent member on the staff of the local health unit, has proved to be of invaluable aid in establishing an overall health program by coördinating the resources of both official and public health agencies within the community. The importance of the rôle played by the health educator has been increasingly recognized by local health officers, many of whom have budgeted funds for the employment of such personnel. But again we face the handicap of an acute shortage of qualified individuals who have a knowledge of both public health and education. To alleviate this situation The National Foundation for Infantile Paralysis has made, since 1944, direct grants to the U. S. Public Health Service totalling \$160,000 to be used for fellowships in public health education. With this support, a total of 58 awards have been made, and many more are needed to meet requirements of expanding health education activities.

The personnel shortage has also been felt severely in public health agencies with regard to orthopedic programs. Supervisory nurses with qualifications in both physical therapy and public health nursing have been most difficult to obtain. The preparation of individuals to fill supervisory posts entails great expense for the agency and for the nurse. In addition, the paucity of teachers of orthopedic nursing has severely limited the development of workers in this field. Only by offering real encouragement to nurses to qualify as directors and instructors of orthopedic nursing courses can we meet the demands of the future.

The National Foundation for Infan-

tile Paralysis is particularly interested in this phase of public health work, for it relies heavily upon the skill of experienced orthopedic nurses to minimize the crippling aftereffects of poliomyelitis and to prevent deformities in its victims. Therefore, since 1940 we have approved a series of grants to the National Organization for Public Health Nursing totalling \$125,950 to train and instruct capable supervisors and directors in orthopedic public health nursing. Up to the present time, 48 scholarships have been awarded, and the National Foundation will continue to support and finance this project which is contributing substantially to the general effectiveness of official health agencies.

Unfortunately, the personnel problem cannot possibly be handled by public health organizations within the limitations of their budgets. The recruiting of qualified individuals is not accomplished in haphazard fashion. For the past 2 years we have underwritten to the extent of \$25,350 the American Public Health Association's field consultation service to state and local health departments in connection with recruitment and selection of personnel and the maintenance of sound personnel procedures.

The same organization was further aided by a 2 year grant of \$10,000 to acquaint city, county, and state health authorities with the importance of the sanitary engineer in maintaining a healthy environment.

It becomes quite evident then that, rather than working in opposition to public health agencies, the National Foundation has maintained a policy of direct assistance in the building of sound, vigorous official organizations, capable of leading the fight against disease within their communities. But it still rests heavily upon voluntary agencies—specialists in their field—to carry on the bulk of the work in combating a specific disease. Every advance that the National Foundation makes against poliomyelitis is an accomplishment in control of all diseases. Every research project carried on with the financial support of the National Foundation is a major effort in the quest for national health. Whether we represent voluntary, private or official health agencies, our goal is the same.

By working hand in hand, by co-operating willingly and energetically, we may look forward to new accomplishments in the service of the American people—and of all humanity.

Coördination of Hospitals and Health Departments

Joint Statement of Recommendations by the American Hospital Association and the American Public Health Association *

THE American Hospital Association and the American Public Health Association have prepared this statement to define the areas in which fuller co-operation and integration of hospitals and health departments may be achieved. The statement is confined to an exploration of these areas and does not concern itself with other aspects of either hospital management or community health organization. It is hoped that hospitals and health departments will find it a useful guide to their attainment of closer working relations in the interests of greater efficiency and improved health service.

Among the foremost institutions which today serve the health of the community is the general hospital. Not only has the hospital developed during the past few decades into the basic institution providing the technical facilities for adequate health appraisal and modern diagnosis and treatment of disease, but it has also become an indispensable workshop for the practising physician. Through its ability to make essential technical procedures available to physicians and other personnel the hospital exercises a strong and direct influence on the quantity and quality of medical and health services.

Because of its important position the general hospital's responsibilities in the

total community health picture have been constantly expanding. In addition to the provision of facilities for medical care of high quality, its functions now include training of medical and allied personnel, medical research, and participation in local public health activities.

Profound changes and advances in the activities of health departments have paralleled this expansion in hospital functions. The achievement and maintenance of ever higher levels of community sanitation is making it possible for health departments to turn increased attention to developing programs to improve individual health through immunization, education, and health supervision; at the same time they have found it essential to provide therapeutic services if communicable diseases such as tuberculosis and syphilis are to be effectively prevented. Health departments have begun to recognize the important public health implications of such major health problems as cancer, heart disease, and other long-term illnesses and to combat them by providing certain facilities to aid in early diagnosis and treatment. In order to secure maximum effectiveness for these campaigns they have begun to develop increasingly closer relationships with hospitals and practising physicians.

Preventive and curative medicine have reached the stage where they are no longer separable, and it is necessary at the present time to bring them together physically and functionally. The close physical and organizational association of health departments and hospitals will

* This report has been approved by the Executive Board of the American Public Health Association on the recommendation of the Committee on Administrative Practice and the Subcommittee on Medical Care. It has been adopted as an official statement of the two associations.

provide a valuable step toward this essential goal.

Hospitals and health departments have a common interest in providing the best possible technical facilities and administrative tools for the further development of both the preventive and therapeutic aspects of medical practice. The expression of this relationship in terms of greater coördination of the activities of hospitals and health departments has already occurred in some communities, but a great deal still remains to be accomplished in this direction.

HOUSING OF HOSPITALS AND HEALTH DEPARTMENTS

Since a considerable increase in the construction of hospitals and public health facilities may be expected in the next few years, it is appropriate that certain advantages of joint housing be pointed out at this time. It is strongly recommended that, wherever circumstances justify and permit, there should be joint housing of hospitals and health departments, and, if possible, the offices of physicians and dentists.

Although coördination of the activities of hospitals and health departments can be accomplished even if they are not closely integrated physically, it is most feasible when there is joint housing of the hospital and health department. The common use of laboratory and clinic facilities, which is difficult to achieve when the two institutions are physically separated, occurs readily when they are housed together. The planning of integrated programs is facilitated by joint housing and their administration is made smoother and more efficient.

Outpost rural areas

The health needs of rural areas which are isolated, thinly settled, and unable to support a general hospital may be met by the construction of outpost health facilities. These facilities would

house the offices of physicians and dentists, diagnostic facilities, the office of the local public health nurse, public health clinics, and in some areas a nursing unit for maternity care and minor illnesses.

The physicians whose offices are located in the outpost facility should be members of the medical staff of the nearest general hospital. Arrangements should be made for transportation of patients from the outpost area to the hospital and for consultation visits by the hospital staff to the outpost facility. Otherwise the outpost personnel may deteriorate professionally owing to their medical isolation or the outpost facility may attempt to undertake functions belonging properly in the general hospital.

Populous rural areas

The establishment of hospitals and public health facilities in many rural areas will require entirely new construction. It is recommended that in these areas hospital and health department facilities be constructed as an integral whole. It is particularly recommended that physicians' offices be included in the new structures so that the time and effort usually expended by private practitioners in shuttling back and forth between office and hospital would be minimized. This arrangement would facilitate laboratory and x-ray examinations of the physicians' patients, prevent unnecessary duplication of expensive technical equipment and make it easier for physicians to consult with their colleagues.*

Many advantages to the public, the health department, and the hospital

* The joint housing of hospitals and health departments has already been effected in a number of areas such as Sonoma, Monterey, and Kern Counties, California, and Washington, Charles, and Wicomico Counties, Maryland. In addition, plans to build combined hospital and public health facilities are under consideration in several counties in California; six districts in Manitoba, Canada; Etowah County, Alabama; Winston-Salem, North Carolina; Schoharie County, New York; El Dorado City, Kansas; and Eaton, Barry, Ionia, Allegany, and Van Buren counties, Michigan.

may be derived from joint housing of hospitals and health departments. A single health and medical center means greater convenience and continuity of service for the public. The pooling of resources resulting from joint housing enables the community to obtain more adequate facilities and better trained personnel than it could otherwise afford.

Through joint housing the hospital achieves greater prestige as the community center for all health and medical activities; it is able to hire a more competent staff by virtue of its increased financial strength and can therefore offer more comprehensive and effective service. Joint housing facilitates follow-up by public health nurses of patients after they leave the hospital, while the medical staff benefits from closer association with public health programs. Furthermore it may stimulate increased public interest in the hospital since more people will visit the institution for health promotion and preventive services rather than as a last resort.

The health officer likewise benefits professionally from more intimate association with physicians engaged in clinical medicine. His health programs receive added impetus from the increased knowledge and interest in public health gained by practising physicians, interns, and nurses. Case finding for public health programs in the hospital wards and outpatient department is facilitated. The health department attains new stature, dignity, and public understanding.

Where the general hospital already exists and health department facilities are needed, it is recommended that the latter be constructed as an addition to the hospital or adjacent to it, and that an understanding be reached between the two agencies concerning joint use of certain facilities in order to avoid unnecessary duplication. This plan, however, may not be practicable in some instances because of the isolated location of the hospital.

While it is administratively easier to combine the rural hospital with health department facilities when both are public institutions, there is little reason why joint housing of voluntary hospitals and public health facilities cannot be achieved.*

Urban Areas

In small cities with one existing general hospital it is recommended that health department facilities be constructed as part of or adjacent to the hospital wherever feasible. It may be more difficult to arrange for joint housing in cities with more than one hospital. Nevertheless, the difficulties are not insurmountable.†

In larger cities public health facilities should, in so far as it is logical and possible, be built as part of or adjacent to general hospitals. Of course this will not be feasible in neighborhoods which do not have hospitals. Where joint housing can be achieved it will have an important effect in improving the coordination and effectiveness of hospital and health department activities.

The cities in which medical schools are located present a special situation. In such cases the principal public health facility should be built on the grounds of the teaching hospital.‡

* In several counties of Maryland, for example, the health department pays rent for that portion of the hospital which it occupies, and the arrangement has proved highly satisfactory.

† In the city of Niagara Falls, New York, which has two voluntary general hospitals, plans are now being considered to construct the principal public health facility adjacent to one of the hospitals and to locate smaller centers at strategic places throughout the city. These plans were formulated with the help of the local medical society and both voluntary hospitals, and received their full approval.

‡ This is the plan followed in Louisville, Ky., where the medical school, teaching hospital, and public health department form a single, integrated medical center. In New York City, five of the municipal public health centers are adjacent to medical schools. The health officers hold faculty positions in the medical schools, and medical students serve clinical clerkships in the public health centers. There is no doubt that considerable advantages accrue to both parties from this arrangement.

PERSONNEL AND ADMINISTRATION

There are many ways in which health department and hospital personnel can work together effectively. In urban areas, for example, coöperative arrangements between hospital social workers and public health nurses can prevent duplication of services and increase efficiency. In rural hospitals and health departments, although medical social workers are not generally employed by the separate institutions, it should be possible to employ a medical social worker to serve both agencies where there is combined housing of the health department and hospital.

In urban as well as rural areas the public health nurse can provide continuity of care for discharged hospital patients by carrying out the treatments recommended by the physician and giving home nursing care and supervision. This is true not only for patients with communicable diseases but for all hospital patients, whether ambulatory or not, who require further home supervision or care. Physicians, hospitals, and health departments should together agree on and carry out simple and effective referral systems.

In many areas the shortage of public health nurses limits the possibilities of this type of service. Nevertheless in some rural communities the public health nurse is able to perform a substantial amount of bedside nursing care. In the cities there has been a significant trend toward the amalgamation of voluntary visiting nurse services with those furnished under the health department program, thereby improving service and increasing the potentialities of physician-hospital-health department coöperation in this field.

There are several ways in which the medical staff of the hospital can contribute to the activities of the health department. Arrangements may be made for members of the visiting staff to conduct specific health department clinics

on a part-time salary basis. Members of the visiting and resident staffs can instruct public health nurses in current medical advances and assist in the health department's educational program by lecturing to community groups. Such service by physicians contributes to the building of a close partnership of physician, hospital, and health department to meet the overall health needs of the locality.

Consideration should be given to broadening the concept of intern or resident training to include a definite period of time spent in a public health department approved for this purpose. This would improve the physician's understanding of the preventive approach to medicine and acquaint him with services available to the public through the health department and other community agencies.

The achievement of closer administrative relationships between hospitals and health departments does not come about automatically but requires careful and continued planning as well as administrative finesse. Where the health department and the hospital are jointly housed but under separate administration, joint conferences should be instituted and definite fields of administrative coöperation outlined to further closer and more harmonious relationships.

In those areas which have a small community hospital and health department the appointment of a single administrator for both organizations may be considered.* There is need for further experimentation in this field.

Closer coördination of the training of health officers and hospital administrators is needed to familiarize health offi-

* In Branch County, Michigan, for example, the health officer is also director of the voluntary general hospital. This arrangement has made it possible to offer sufficient compensation to attract a competent physician. It has also proved highly advantageous in achieving greater coördination of hospital and health department activities and a better quality of administration.

cers with hospital problems in view of their increasing responsibilities for hospital planning, construction, inspection, and licensure, and to develop hospital administrators and health officers who have sufficient understanding of each other's activities to coördinate them effectively. This would also make available personnel competent to direct combined hospital-health department units. Several schools of public health have already recognized the importance of such coördination by requiring one basic course of training for both groups and permitting specialization subsequently in either public health or hospital administration.

PREVENTION OF COMMUNICABLE DISEASE

The control of tuberculosis, venereal disease and other communicable diseases affords numerous opportunities for joint action by hospitals and health departments. Tuberculosis and venereal disease clinics belong properly at the general hospital, not at the city hall or some other non-medical institution. Likewise rapid treatment centers for syphilis should, in so far as possible, be housed in general hospitals rather than organized separately.

With present knowledge of the control of cross-infection there is very little reason for establishing special hospitals for the care of acute communicable disease. With the possible exception of large urban centers such special hospitals are economically wasteful and seldom provide services which meet the total medical needs of the patient. A more rational approach is to use general hospital beds for the care of patients with communicable disease and to obtain the assistance of the health department in developing effective isolation techniques. Such coöperative action will be facilitated if the hospital appoints the health officer to its medical staff as consultant in communicable diseases.

Routine chest x-rays as well as sero-

logical tests for syphilis ought to be undertaken by all hospitals. The interest of the health department in these health protection activities should take the form of substantial financial and technical aid. With such assistance every hospital can become a strategic center in the community attack on tuberculosis and venereal disease.

Close working relationships between general hospitals and tuberculosis sanatoria are necessary to afford sanatoria patients the advantages of modern surgical therapy as well as consultation services. For similar reasons a portion of the newly established hospital beds for tuberculosis should be located in or closely connected with general hospitals.

Laboratory service is essential to communicable disease control as well as to the proper functioning of hospitals. Health departments and hospitals have a vital interest therefore in the planning and development of adequate laboratory service.*

In some states hospital as well as health department laboratories are approved by the state department of health which, in addition, holds an annual educational meeting of laboratory directors and supplies them with current bibliographies on technical subjects. Marked improvement in laboratory standards has resulted from such procedures and they have been well received by hospital laboratory personnel.

PROGRAMS FOR NON-COMMUNICABLE DISEASE

With the progressive conquest of many communicable diseases attention has shifted to other major causes of

* In some of the rural counties of Maryland, the use of a joint laboratory has been found to be advantageous, since the additional financial resources allow the utilization of better trained personnel. In small cities with more than one hospital as, for example, Jamestown, N. Y., it has been found effective to have a single director administer the health department laboratory as well as the several hospital laboratories. This arrangement provides a well integrated laboratory service and enables the community to obtain a director of high caliber.

disability and death. Heart disease, cancer, and mental illness are rapidly becoming recognized as having significant public health implications. The epidemiological study of such diseases—their prevalence and relation to socioeconomic, environmental, and constitutional factors—can shed much light upon their origin, prevention, mitigation, and treatment. The social effects of non-communicable diseases, their chronic nature in many instances, their increasing importance as the population ages and the huge expense involved in their care put them beyond the scope of the individual physician or hospital alone and mark them clearly as among the most important public health problems of the day. Accordingly, there have been renewed attempts to construct adequate systems of morbidity reporting and greater emphasis has been placed on health education as a preventive device in the management of non-communicable disease.

Hospitals provide an effective environment in which to educate the public in health matters.* In addition hospitals are repositories of much valuable information on the incidence of disease which should be studied and utilized in the development of control programs. They occupy an important position in relation to plans for controlling heart disease and cancer and are natural locations for cardiac and tumor diagnostic clinics. The recent development of cancer detection clinics, in which apparently well persons receive thorough diagnostic examinations, promises to encourage greater concentration on this type of preventive activity by the staffs of general hospitals.

It has long been recognized that psychiatry suffers through its isolation from general medicine. Similarly the aver-

age physician, having received little or no training in psychiatry, is handicapped in his ability to recognize, treat or prevent mental disease. The importance of mental illness is indicated by a recent estimate that approximately 1 patient out of every 28 new admissions to general hospitals, and 1 out of every 16 new admissions to outpatient departments presents problems requiring the services of the psychiatrist.

Owing to the passage of the National Mental Health Act a large-scale development of research facilities and clinics for mental hygiene may be expected. In many areas the local and state health departments will be responsible for administering the mental health program and integrating it with other health activities. It will be to the best interests of psychiatry and medicine in general if hospitals welcome the establishment of mental hygiene clinics and incorporate their functions as part of a general hospital service. Large general hospitals should establish psychiatric services for observation and treatment of mentally ill patients and, wherever feasible, the medical staffs of general and mental hospitals should develop liaison in order to provide consultation services to patients of mental institutions and to furnish the patients of general hospitals with skilled psychiatric assistance. In this way a more fully generalized and comprehensive service to the community would be achieved.

MATERNAL AND CHILD HEALTH

Maternal and child health clinics should be easily accessible to the persons served and many must be conducted in communities or neighborhoods which do not have hospitals. Nevertheless, there are numerous instances where the general hospital is easily accessible but is not utilized for such services. This situation, which has arisen from the separate development of hospital and health department facilities, prevents both hos-

* This has been demonstrated by the excellent programs of The Johns Hopkins Hospital in Baltimore and the Shoemaker Clinic in Cincinnati.

pital and health department from operating at their maximum effectiveness in the protection of maternal and child health. Health department prenatal clinics for the adjacent neighborhood should be conducted in the general hospital in order to insure continuity of care, easy transfer of records, and adequate postpartum follow-up. Similar considerations apply to well child and pediatric diagnostic and treatment clinics. The maternal and child health clinics conducted by health departments in areas not easily accessible to hospitals should be affiliated with the central hospital clinics for referral of complicated cases.

Still other opportunities exist for closer relationships between hospitals and health departments. The latter can supply educational literature to hospitals for distribution by physicians to their maternity patients. The state department of health in particular can furnish consultation services by medical, nursing, nutrition, and other staff members. Hospitals can enlist the aid of the health department to prevent outbreaks of infant diarrhea and to develop comprehensive programs and facilities for the specialized care of premature infants, and should cooperate with the health department and practising physicians in their review of maternal and infant deaths. The health department can assist hospital laboratories to make determinations of the Rh factor by furnishing consultation services, providing typing sera, or actually performing the tests.

All too often the public health nurse receives notice of the birth of a child several weeks after its occurrence and the mother is thereby deprived of her advice and assistance during the period when they are most important. This problem has been solved in some areas through cooperative arrangements by which the health department is informed of the birth before the mother and child leave the hospital. In many communities arrangements have been made with

physicians and hospitals for the public health nurse to see the mother while she is still in the hospital as well as make a preparatory visit to the home, thereby establishing the best possible conditions for adequate home follow-up.

The proportion of home deliveries is still too high in many areas. Hospitals should give serious attention to the provision of sufficient maternity beds to meet the needs of the entire community, particularly for the care of complicated cases.

MEDICAL CARE AND HOSPITAL SERVICES

A number of specialized medical care programs, including those for communicable disease, tuberculosis, venereal disease, and crippled children, are recognized responsibilities of health departments, and it is desirable that they be entrusted with new programs of community medical care which may be assumed by various levels of government. It would seem wise therefore for hospital and health authorities to undertake intensive research on several mutual problems. One of these, for example, is the creation of a satisfactory cost accounting system which will be equitable to both the hospital and the health department.

The experience of the last few years, particularly with the Emergency Maternity and Infant Care program, has established the important principle that the hospital receive full cost for the care of patients for which government assumes full responsibility. This precedent should be followed in all public medical care programs provided that an agreed standard of care is established and there is proper cost accounting.

In approximately three-quarters of the states the state health departments have been given the responsibility for hospital surveys and planning incident to the Federal Hospital Survey and Construction Act of 1946, and it is expected that they will be given similar

administrative responsibilities with respect to the construction phase of the program. This will inevitably encourage much closer relationships between hospitals and health departments than have ever existed in the past.

Hospital licensure laws have already been enacted in most states and with few exceptions the state department of health has been designated as the responsible agency. Much of the activity of the agencies administering such laws is of an educational character, designed to assist hospitals in improving standards of service to the public.

A significant expansion in the number of full-time local health departments as well as in the scope of their activities may be expected in the next few years. Similarly the nation's hospital system will be extended to many areas which now lack adequate facilities and greater emphasis will be placed on the community responsibilities of the general hospital. It is important at this time that hospital and health department administrators plan to achieve maximum co-

ordination through joint housing, coöperative use of personnel, and the development of active programs to safeguard and promote the health of their communities.

SELECTED BIBLIOGRAPHY

General Relationships

1. Relations Between Health Departments and Hospitals *A.J.P.H.*, 18:290 (Mar.), 1928.

Report of a joint committee of the American Hospital Association and American Public Health Association with results of a study of coöperative relationships in regard to clinics, laboratories and hospitalization of communicable disease.

2. Report of the Committee on Public Health Relations, American Hospital Association. *Tr. Am. Hosp. A.*, 38:104, 1936.

Excellent recommendations for coördinated activities in hospitalization of communicable disease, laboratory service, medical social service, clinics and outpatient departments, maternal and infant care, venereal diseases, cancer, diabetes, tuberculosis, cardiac diseases, mental hygiene, etc.

3. Hospitals and Health Departments. Commission on Hospital Care. *Hospital Survey News Letter*, Aug., 1946.

A brief and concise analysis of the need for closer coördination, with concrete suggestions in regard to personnel, facilities, administrative relationships, and specific integrated programs.

Housing

4. Hospital Survey and Construction Act of 1946.

Text of Public Law 725, 79th Congress and text of regulations issued by the U. S. Public Health Service.

5. The Public Health Center and the Community Hospital. V. M. Hoge. *Mod. Hosp.*, 63: 56 (Aug.), 1944.

Describes the advantages of building combined hospitals and public health centers in rural areas. Includes plans of a 50 bed rural hospital and health center.

6. Hermann M. Biggs' Contribution to the Modern Concept of the Health Center.

M. Terris, *Bull. Inst. Hist. Med.*, 20:387 (Oct.), 1946.

Description of Hermann M. Biggs' health center proposals of 1920, which included hospital and health department facilities in a single center.

7. The Health Center—Adaptation of Physical Plants to Service Concepts. J. W. Mountin, and August Hoenack. *Pub. Health Rep.*, 61:1369 (Sept. 20), 1946.

Discussion of four types of health center plans:

1. Those designed for public health agencies alone
2. Those that combine the hospital and public health agencies
3. Those that provide accommodations for the health department and practising physicians

4. Those that combine the health department, the hospital, and offices for practising physicians

8. Hospitals. U. S. Public Health Service. Reprinted from *Architectural Record*, Aug., 1945.

Blueprint of a coordinated hospital service plan, including plan suggestions for a 50 bed rural hospital and public health center and an outpost rural health center with 10 bed nursing unit.

9. Better Hospital Care for the Ambulant Patient. Hospital Association of Pennsylvania, Harrisburg, Pa., 1946.

Study of clinic services in Pennsylvania, with comprehensive discussion of the role of hospitals in relation to group clinics, health centers, and civilian rehabilitation.

10. Schoharie County Health Service. New York State Department of Health and the Joint Hospital Board, Sept., 1946.

Detailed report to a county board of supervisors on a combined hospital-health department unit.

Specific Programs

11. The Care of Acute Communicable Diseases in General Hospitals. Commission on Hospital Care, *Hospital Survey News Letter*, Jan., 1946.

A good analysis of the reasons why patients with acute communicable disease should be cared for in general hospitals.

12. Tuberculosis Control. *Hospitals*, Aug., 1946.

A portfolio of information on tuberculosis control prepared in collaboration with the U. S. Public Health Service, with special emphasis on the role of general hospitals and the routine use of admission chest x-rays. Articles on methods, finances, records, etc.

13. Health Education in Hospitals and Out-Patient Departments. Henriette Strauss. *A.J.P.H.*, 35:1175 (Nov.), 1945.

The experience of the Department of Preventive Medicine at The Johns Hopkins School of Medicine in organizing a health education program in the hospital.

14. Education While They Wait. Elisabeth M. Ferber. *Mod. Hosp.*, 66:63 (Apr.), 1946.

The use of motion pictures as a health education medium in the Shoemaker Clinic in Cincinnati.

15. Hospital Licensing Act. Council of State Governments, Chicago, Jan. 1, 1947.

A model hospital licensing act prepared by the Council of State Governments in cooperation with hospital, public health, and medical organizations.

PROGRESS IN THE STUDY OF ORGANIC INSECTICIDES

TWO years ago, Dr. F. C. Bishopp¹ reviewed for us the status of DDT as a public health insecticide; and progress in this field has been so rapid that we have asked Dr. J. M. Andrews of the U. S. Public Health Service Center at Atlanta to bring the subject up-to-date, in the Special Review Article of this issue of the *Journal*. The importance of such a review is indicated by the fact that Dr. Andrews cites 134 articles bearing on the subject, most of them appearing within the past two years.

The use of DDT has been brilliantly justified by recent experience, particularly in dealing with malaria, with murine typhus, and with various diseases carried by sandflies. It has been useful in the control of the house-fly, but with certain distinct limitations, which the sanitarian should bear in mind. DDT is not effective against the larvae of house-flies and blow-flies, and certain strains of house-flies appear to develop special resistance against this insecticide in the adult state, a phenomenon analagous to the evolution of drug-resistant strains of various pathogenic microbes. It is clear that fundamental sanitary measures for the control of fly breeding cannot be neglected.

Dr. Andrews reviews suggestive studies of various solvents used with DDT and of new alternative insecticides such as Chlordane and DDD. He notes the importance of guarding against toxic effects, although "DDT when used as an insecticide, with reasonable intelligence and the precautions normal to the use of modern insecticides, is harmless to man and animals." He emphasizes the need for regulating dosage, when insecticides are applied on a large scale over wide unoccupied areas to destroy insects harmful to health, forest trees, or agricultural crops, so as to avoid upsetting the general balance of wild life.

All in all, we believe that this review will be of unusual value to our readers. The use of the new insecticides marks one of the major advances in the history of public health; and it inaugurates a far-reaching change in sanitary practice through the replacement of rule-of-thumb (or rule-of-nose?) nuisance control by scientific sanitation.

THOMAS PARRAN

THE United States Public Health Service has a history of a century and a half behind it (although for the first part of that period it was called the Marine Hospital Service and performed only the function of providing medical and hospital care for sailors of the Merchant Marine). Hugh S. Cumming, Surgeon General from 1920 to 1936, transformed the organization from a sound but somewhat pedestrian service to a vital and progressive one; and many of the outstanding leaders of the U. S. Public Health Service were brought forward to positions of influence under his regime. "Tom Parran," who succeeded him has presided with wise vision and courageous initiative over the most distinguished era in the history of the Service.

The following brief chronological list of the major new ventures undertaken during the twelve years of General Parran's service (which ended this spring), is an impressive record:

1937. Initiation of a National Research Program on the cause and cure of cancer.

1938. Initiation of a National Program for the control of venereal diseases (in which Dr. Parran's personal leadership was particularly influential in breaking down old prejudices and which has made most fundamental contributions to the administrative application of modern rapid-treatment methods).

1943. Organization of the United States Cadet Nurse Corps, which was of great value in meeting war needs.

1943. Radical reorganization of the structure of the Service, to secure greater efficiency in operation.

1944. Initiation of a National Tuberculosis Control program.

1946. Initiation of a National Mental Health Program, probably the most effective step ever taken in this or any other country; to translate talk into action in this most important and most neglected field of public health.

1947. Actual initiation of a nation-wide survey and construction program to develop essential hospital and health services for neglected areas.

Meanwhile, the outstanding program of research, at the National Institute of Health, has been continued and expanded, so that this Institute represents the most fruitful research agency in the field of public health anywhere in the world. Grants-in-aid to states, local health services, and institutions for expansion of public health work and research have averaged 13 million dollars a year in recent years, while for the same period expenditures by states have increased from 16 to 52 million dollars a year.

Dr. Parran had been released from 1930 to 1936 to serve as Commissioner of Health of the State of New York, where he built up—on the foundation laid by Hermann M. Biggs—one of the most outstanding state health departments in the country. In recent years he has made notable contributions in the field of international health, and presided at the New York conference where the Constitution of the World Health Organization was drafted in 1946. It is as the "S.G." however, that he is most widely known to us. It was primarily for his leadership of the U. S. Public Health Service that he received 16 honorary degrees, and the Sedgwick Medal and the Lasker Award from our Association. With no prejudice to his predecessors who served in less health-minded years, Thomas Parran stands today as the most outstanding Surgeon General of the world's most outstanding national health service. He is a young man of whom we shall hear more in the future.

THE BATTLE OF BRITAIN

THE new British National Health Insurance Act will come into force on July 5, replacing the present National Health Insurance program which on that date goes out of existence. At the present writing, the British Medical Association plans to refuse participation, supported by a two million dollar Fighting Fund (described by the lay press as a "Strike Fund"). Feeling on both sides is bitter. The *British Medical Journal* raises the cry of governmental dictatorship, and frankly appeals to "emotion as the driving force behind reason and action." The *New Statesman* says that the British Medical Association is "seeking to debase" the generous motives which animate the healing art "by arousing emotions which, when they are sincere, are mistaken, and, when they are less than sincere, are a betrayal of the doctor's calling and of the loyalty and affection of his patients."

The conflict is a tragic one; and it is important for us, in the United States, to understand what the shooting is about. Many Americans have been led to believe that it concerns the basic principles of compulsory health insurance; but this is not the case. England has had compulsory health insurance for more than thirty-five years. "All concerned, doctors as well as public, recognize the need for a National Health Service; all accept broadly the structure of the Act in regard to the whole hospital system; all realize that there must be a public medical service based wholly or mainly on capitation fees. This is as it should be; fundamentally this is a good Act; its provisions are better than most previous proposals and it gives to doctors themselves a far larger representation than they did have—on Executive Councils, Appeal Tribunals, Medical Practices Committees, and the rest—in the administration of the Act."¹ The negotiating committee of the medical profession itself pointed out that "such differences as have arisen between the government and the main body of the profession relate not to the objective itself (the establishment of a comprehensive medical service), but to the means proposed to achieve the objective."

The issues which divide the medical profession from the government are four in number:

The first of these, and the one which perhaps bulks largest in discussion, is the provision of the Act which establishes a basic salary of 300 pounds for every physician, to which will be added capitation fees based on the number of families served. It is estimated that a moderate practice should yield a total income of 2,000 pounds. The basic salary is included in the Act to make sure that the young physician just starting in practice shall have at least a minimum income while he is building up his panel practice. The British Medical Association resents this as an "entering wedge" for the principle of salaried service and proposes a higher capitation scale as an alternative.

A second bone of contention is the provision in the Act that practices built up on a panel basis in the future cannot be sold by a retiring physician to a potential successor. (The government has arranged to recompense all physicians for the cash value of practices existing prior to July.)

A third point of conflict is the provision in the Act that if a physician wishes to move to a new area, he cannot take a panel practice in that area without the permission of the committee representing the panel doctors in that area. Private practice for the well-to-do, as well as consulting service by specialists, will be, of

course, entirely free; and the decision whether local panel practice is sufficient to warrant an additional panel practitioner is made, not by any government official, but by the local panel practitioners themselves. A fund of 400,000 pounds is provided for inducements to physicians to serve in "under-doctored" areas.

Fourth, the British Medical Association objects to the fact that the decision of a local executive committee (50 per cent medical) to remove a physician's name from the panel list can be appealed only to a special tribunal composed of a lawyer appointed by the Lord Chancellor, a medical practitioner appointed after consultation with the medical organizations and a third, with experience in local executive committees. A decision of this tribunal unfavorable to the physician concerned may be vetoed by the Minister of Health, but not a decision favorable to him. The British Medical Association demands further appeal to the lay courts.

There have been certain minor points at issue; but these are the four major factors which threaten to produce a "Doctor's Strike" in Britain next July.

No one in this country can fully evaluate the issues involved; but such journals as the *London Spectator* give us a picture of the trend of public opinion in quarters sympathetic with the medical profession. Such opinion is reasonably unanimous in supporting the Minister of Health on points 3 and 4 above (avoidance of excessive competition for panel patients in an "over-doctored" area and prohibition of the sale of public panel practices). The opposition of the British Medical Association to these two provisions seems to have little public support. On the fourth point, right of appeal from the Minister of Health to the Courts on the part of the practitioner removed from a panel, public opinion seems generally to back the new Act; it would seem, however, that a concession on this point to the British Medical Association would not do anyone serious harm.

The first issue listed above, the basic 300 pound salary, would also appear to be properly open for conference and possible reconsideration. The purpose of this provision is an excellent one. Such a salary was included in the report of the Medical Planning Commission, representing the British Medical Association and other medical bodies, in 1942. Yet the present opposition to this basic salary is so strong that its elimination or modification might well be considered.

The *London Spectator* said—before the result of the doctors' plebiscite was known—"It is of cardinal importance that the Act shall come into force on the appointed date, now less than five months distant, and that it shall be worked not by men driven into a corner against their will, but by a body of practitioners determined under conditions which satisfy them to do their best for the health of the nation, as every doctor is doing today. Difficult as the situation is, there is no reason why this should not happen, for sharp though certain outstanding differences may be, none of them is incapable of adjustment. There can be no ultimatum to the doctors; nor can there be one by the doctors. When the result of the plebiscite is known some kind of contact between the Minister and British Medical Association must be reestablished. And the public, for whom this Act was devised and who need it urgently—particularly that large middle class, uncovered by National Health Insurance, on which a long illness or a serious operation falls with such crushing financial weight—must insist that outstanding questions be thrashed out between reasonable men in a spirit of common sense."

THE JOURNAL INDEX

THE last issue of this *Journal* was devoted to books; but to the scientist in any field periodical literature is equally important, and often more difficult to find when you want it. How often have you wondered where you saw that typhoid epidemic described or where that excellent article on health education appeared?

You will find the answers, so far as our *Journal* is concerned in a complete Index of its first 35 volumes (1911-1945). The preparation of this Index by Louise Pickens Tanner and Fred Wilbur Tanner has been a labor of love for which the Association owes these authors a deep debt of gratitude. It covers original communications, editorials, committee reports, and Association news, cross-indexed by subject and author; and occupies 335 pages of text. Here, you can find reference to what Biggs said about tuberculosis in France in 1918, to what Chapin wrote about air and contact infection in 1912, and to Sedgwick's Presidential address in 1913. This volume will be invaluable for our members and for students of public health in every country.¹

Clearing House on Public Health Salary Information

Salaries in State Health Departments

IN February the State and Territorial Health Officers Association released the study of salaries of state public health workers prepared at its request by the U. S. Public Health Service.

The study represents actual salaries paid* state health officers, 9 selected program directors, and 6 occupational groups of public health workers in the employ of state health departments in November, 1947 — medical, nursing, sanitary engineering, sanitation, nutrition, and professional laboratory personnel. The study does not represent a detailed job analysis of positions. It is therefore based on comparable titles which do not always represent comparable levels of responsibility. In spite of its lack of statistical refinements, this study serves a useful purpose in focusing attention on salaries.

Nor does the study indicate desirable salary levels. For practically all titles studied the salaries range widely among the 48 states. The highest salaries paid by a few states may not be within reach of all states, but it is certain that in most instances median salaries or less will not produce substantial responses from applicants.

The data of the study are shown entirely in the form of charts. These are of three kinds: bar charts showing in descending order the amount paid state health officers and bureau directors in 9 categories; bar charts showing salary ranges for 8 groups of workers in rela-

tion to number of persons in each salary class; and tables showing number of workers in the eight groupings in various salary classifications in each state, the states grouped in the U. S. Public Health Service Districts.

State health officer annual salaries range from \$5,000 to \$15,000, but in only 7 states were they as high as \$10,000. These states are in New England, the Middle Atlantic, South Eastern, and Pacific Coast regions. The median was \$7,500 which is also the mode and was paid by 10 states. In 17 states the health officer's salary was less than \$7,000, and in 6 states less than \$6,000. For directors of local health services salaries ranged from \$4,500 to \$9,600.

Of the directors of medical specialties, the director of tuberculosis control activities appears to be slightly in the lead. The range of salaries and the number in certain salary groupings are shown in Table 1 for three groups of medical specialties.

No medical personnel other than state health officers received more than \$9,000 except in one state. One such worker in each of 3 states in 3 different regions was paid less than \$3,600. A total of 133 workers, one-sixth of the number in this category, received less than \$5,000. These salaries were scattered among all regions except the Pacific Coast states.

State directors of sanitary engineering, of whom 47 were reported, were paid salaries ranging from \$4,250 to \$11,000. The median, paid in 3 states, was \$6,000. Nine state sanitary engineers

* Except in some instances in which position was vacant and minimum rate shown in the State Compensation Plan was used.

TABLE 1

| | <i>Maternal and Child Health Service</i> | <i>Venereal Disease Control</i> | <i>Tuberculosis Control</i> |
|----------------------------|--|---|---------------------------------|
| Number of States Reporting | 47 | 39 | 38 |
| Highest Salary | \$7,750 | \$9,200 | \$11,700 |
| Lowest Salary | 4,200 | 4,200 | 4,500 |
| Median Salary | 6,250 | 6,000 | 6,300 |
| Number Receiving | | | |
| \$7,500 and over | 2 | 3 | 6 |
| Less than \$6,000 | 18 | 15 | 11 |
| Less than \$5,000 | 7 | 6 | 4 |

received \$7,000 or more; 12 received less than \$5,000.

The median salary of the 446 sanitary engineers below the rank of directors was between \$4,000 and \$4,200; 44 per cent of the entire number received less than \$4,000 and one-seventh received \$5,000 or over. Seven persons in this category received \$7,000 or over. Nearly half of the salaries ranged between \$3,600 and \$4,400.

For this group of workers the median was the same in all areas except the Pacific Coast states where it was \$4,200–\$4,400 and the Mountain states with \$4,000. These two areas are less significant because of the small numbers involved.

Sanitation personnel is treated as a separate category throughout the study. In the effort to get a reasonably homogeneous group, veterinarians, entomologists, rodent, bedding, and drug and narcotic inspectors were omitted. Even this group of 1,388 workers represents a wide range of salaries and presumably also of qualifications.

Salaries of this group range from \$1,440 to \$9,200 with both the median and the mode between \$2,400 and \$2,600. Fewer than 1 per cent received more than \$5,000; and one-fourth less than \$2,400. Median salaries for this group vary rather widely for the different regions of the country. Only in the Eastern and Southern states, which employed two-thirds of the reported workers in this category, is the median as low as the national median.

In the Mountain, West North Central, and South West states the median is \$2,600–\$2,800; in the East North Central, \$3,000–\$3,200; and in the Pacific Coast states \$3,200–\$3,400.

This material also shows an interesting relationship between sanitarians and sanitary engineers. For all of the states a ratio of one engineer to three sanitarians is indicated by the figures. The range however is from practically an equal number of engineers and sanitarians in the East North Central states to more than six sanitarians per engineer in the 12 Southern states.

The ratios are shown in Table 2 by the U. S. Public Health Service districts:

TABLE 2

| <i>U. S. Public Health Service District</i> | <i>Engineers</i> | <i>Sanitarians</i> | <i>Ratio of Sanitarians To Engineers</i> |
|---|------------------|--------------------|--|
| Total | 446 | 1,388 | 3 |
| 1 | 124 | 278 | 2+ |
| 2, 4 | 102 | 649 | 6+ |
| 3 | 92 | 117 | 1+ |
| 5 | 20 | 56 | 3– |
| 7, 9 | 100 | 245 | 2+ |
| 8 | 8 | 43 | 5+ |

Laboratory personnel is divided into directors and one other group limited to professional workers. Forty-five states reported directors of laboratory services with salaries ranging from \$3,600 to \$10,000. The median was \$6,000. Twelve states paid less than \$5,000, and only 6, \$7,000 or more.

Nearly one thousand of the workers other than directors were reported with salaries ranging from less than \$1,400 to more than \$7,400. The median was between \$2,800 and \$3,000 and the

Credit Lines

FURTHER LIGHT ON THE PECKHAM HEALTH CENTER

The Pioneer Health Center in London (otherwise known as the Peckham Health Center) has been discussed in connection with the centennial meetings of the Community Service Society of New York which brought Dr. Innes H. Pearse and Dr. G. Scott Williamson to New York in March. The following notes supplement the information that is available in the volume *The Peckham Experiment—A Study in the Living Structure of Society*, by Innes H. Pearse, M.D., and Lucy H. Crocker, B.Sc., published by Yale University Press, 1945, 333 pp., price, \$3.50. (See *A.J.P.H.*, 34, 10:1103 (Oct.), 1944.

A conversation between the executives of national health agencies and Dr. Pearse brought out the following interesting factors:

Throughout the development of this plan the interest has been focused on insusceptibility rather than on susceptibility to disease. The center of interest is health rather than disease. The family is the unit, for all the thinking and planning and experience has shown that the earlier recognition of various derangements, both physical and psychological, gives a great advantage in prompt action and correction.

Dr. Pearse believes that the causation of disease lies as much in the environment as in the individual.

Being reluctant to invade the homes for case work, the group set up a recreational club to bring the people out on their own volition and to provide a center where the medical services could be carried out. Two thousand families have been included in this service, made up of about 8,000 individuals. A so-called "overhaul" examination was carried on 5 days a week from 2 to 10

p.m. Throughout this examination that which was right in the individual's health was sought rather than that which was wrong. In about 10 per cent of the persons nothing wrong appeared but this 10 per cent that was physically and mentally normal was not necessarily made up entirely of mature and well adjusted individuals.

Of the entire group, about 20 per cent came in with some disease or complaint and experience showed that at least half of these conditions were unknown to the medical profession. In this particular group money was not the primary reason for keeping people away from medical care.

One of the most prominent developments was the improvement shown by women in the capacity to carry on during pregnancy so far as family responsibilities were concerned.

The service made a point, since the family was a unit, not to forget the father of the family, who is usually away at work during the ordinary clinic hours.

A very clever means of admitting only those who were members and whose dues were paid was devised in individual keys for the door which automatically registered the attendance of the individual and would admit him only if his dues were paid. This method was also used in the study inside the center in studies of what is called the "Action Pattern."

A motion picture describing the Pioneer Health Center under the title of "The Center" is available in the United States from the Offices of the British Information Service, 30 Rockefeller Plaza, New York City.

ETCETERA

If you do not see the *Statistical*

Bulletin of the Metropolitan Life Insurance Company regularly, you should. Just as an example, the November, 1947, issue discussed "The Tuberculosis Problem—Retrospect and Prospect," the theme of which is "The time is ripe for an all out war to stamp out tuberculosis in our country," and significantly, "Side by side with these specific measures is the general effort to provide better housing and better living and working conditions generally for the people of our country."

Other articles in this issue are "The Chances of Being Born Alive," which we are told are determined by a variety of factors, among them "order of birth"; another estimates that the cost of the common cold is over a billion dollars a year and thus "must be rated high in the list of enemies of the public health."

The same issue reports a sharp increase in motorcycle accident fatalities, and on the other hand a decline in mortality from toxic goiter.

SOUTHWESTERN MINNESOTA HEALTH DAY

"Health Day" may come to be a technique for organizing communities to meet their health problems. At any rate, a group of six counties comprising the Southwestern corner of Minnesota along with the Southwestern Minnesota Medical Society and its Women's Auxiliary and the Minnesota Department of Health State District Health Unit in that area tried this technique late in February. Representatives of the Minnesota School of Public Health, farm and labor groups, public schools, nursing and welfare agencies, and representatives of the state health department all met in Worthington to discuss "Our Community Health Problems," "Farm and Home Safety," and "Mental Health in Child Development." The six counties participating in this "Health Day" have a total population of about

100,000 and make up one of the State District Health Units. This experiment in coöperation might be a first step in setting up a local district health unit. Further information can be secured from The Division of Public Health Education, Minnesota Department of Health, Minneapolis 14.

DOCTORS CONSIDER THEIR SOCIAL RESPONSIBILITY

"The Plight of the Negro Physician in American Medicine" was the subject of a recent public discussion held at the New York Academy of Medicine under the sponsorship of the Physicians Forum. Speakers were:

Montague Cobb, M.D., Professor of Anatomy at Howard University
Alfred E. Cohn, M.D., Rockefeller Institute for Medical Research
Curtis Flory, M.D., Chairman, New York County Chapter of the Physicians Forum's Committee on Civil Rights in Medicine

It is heartening to see physicians take some responsibility for understanding—and perhaps doing something about—the disadvantaged members of their profession.

"THE ANNUAL," WESTERN BRANCH A.P.H.A.

There has recently come from the press, under the auspices of the Western Branch American Public Health Association, a first issue of *The Annual*, representing a résumé of papers presented at the first post-war meeting of the Western Branch held in San Francisco in May, 1947. This excellent publication was made possible through the contributions of several pharmaceutical houses to the Western Branch.

The five chapters include papers on Preparation for Public Health, on Mental Health and Geriatrics in a Public Health Program, on Public Health Administration, on Housing and Community Planning, and on Communicable Diseases. Included are the

Presidential Address of Karl F. Meyer, M.D., and the address of Thomas Parran, M.D., Surgeon General, U. S. Public Health Service, on Expanding Responsibilities and Opportunities in Public Health. Other contributors are Drs. Charles E. Smith, Harold D. Chope, Edward S. Rogers, Robert H. Felix, Kent A. Zimmerman, Lester Breslow, Alfred M. Popma, Howard West, Florence R. Sabin, Malcolm Merrill, Arthur Ringle, L. J. Lull, J. S. Cull, Raymond V. Stone, Richard K. C. Lee, James H. Steele, W. R. Giedt, G. L. Dunnahoo, and William McD. Hammon. The field of health education was covered by Dorothy B. Nyswander, Ph.D., that of graduate training in the West for nurses by Miss Mary J. Dunn, that of engineering training by Professor Harold B. Gotaas, and housing by Charles L. Senn and Allan A. Twichell.

The officers of the Western Branch are to be congratulated on having produced so commendable a volume in spite of the difficulties. The Publication Committee was under the Chairmanship of Richard A. Koch, M.D., San Francisco.

"CRADLE TO THE GRAVE" SOCIAL SERVICES OUTLINED

If, as has been said, a country may be judged by the way it cares for its children and its aged folk, there is plenty of evidence now available for judgment to be passed on modern Britain.

The evidence has just been summarized in a pamphlet *Social Services in Britain*, produced by the British Information Services, 30 Rockefeller Plaza, New York 20. This summary not only includes welfare schemes for the very young and the very old in Britain, but also the new security measures covering the sick, the unemployed, expectant and nursing mothers, widows, parentless children, the industrial injured, and even the decent disposal of the dead.

In other words it demonstrates Britain's claim to care for its citizens "from the cradle to the grave."

PREVENTIVE MENTAL HYGIENE IN WELL BABY CLINICS

Beginning in October, 1947, the Baltimore City Health Department in its Eastern Health District began a program designed to make preventive mental health a part of the general public health services offered in the well baby and maternity clinics. Before the program was started seminars were held for physicians and nurses to outline preventive mental hygiene possibilities in their maternal and child health work.

This program, together with an "Outline of Mental Hygiene in Maternal and Preschool Child Health for Public Health Nurses" is described in *Baltimore Health News* (25:1-2 (Jan.-Feb.), 1948), which is available from the Baltimore City Health Department, Municipal Building, Baltimore.

DISINFECTING WATER MAINS

"A Procedure for Disinfecting Water Mains," appearing in the February issue of the *Journal of the American Water Works Association*, is a report approved by the A.W.W.A. Board of Directors on September 30, 1947. It suggests both preventive and treatment procedures to minimize the possibility of contamination of a water system. The laying of new systems and repairing of existing ones are also covered.

ENGLISHMAN SUGGESTS A HYGIENIC FORK

The author of *A Hygienic Fork*, I. Gordon, M.D., Edin., Deputy Medical Officer of Health, Ilford, Essex, England, calls attention to the fact that very little change has been made in the design of tableware as a means toward better eating utensil sanitation. He suggests a three pronged dinner fork having tines half the length of those in the con-

ventional fork, with the edges and bases of the prongs bevelled for greater ease in cleaning. This article appears in the August 9, 1947, issue of *The Lancet*, a weekly British medical journal.

BERNARD BARUCH ON MEDICAL CARE

The Committee for the Nation's Health has made available reprints of Bernard M. Baruch's address on *Medical Care for the People of America*. This was recently delivered at a dinner sponsored jointly by the Medical Society of the State of New York, The Coordinating Council of the Five County Medical Societies of Greater New York, and the Greater New York Hospital Association. In this he says "I would not be frank—nor friendly—if I did not add what you know. Voluntary health insurance is not enough." Available from Committee for the Nation's Health, 1790 Broadway, New York 19.

A SURVEY OF OPERATING DATA FOR WATER WORKS IN 1945

The February, 1948, issue of the *Journal of the American Water Works Association* reports on a survey of basic financial statistics of water works systems in the United States. This survey is based on a report of a committee authorized by the Board of Directors of the A.W.W.A. These data were compiled from questionnaires sent to the executives of properties in the United States serving communities of 10,000 or more. Of these, 462 were returned, representing approximately 50 per cent returns. Data for each community on population served, source of water supply, controlling agency, volume of water provided, expenses, and income are included.

PUBLIC HEALTH IN BRAZIL

Several articles on tropical medicine and sanitation in Brazil are contained in the July, 1947, volume of the *Journal of the Servico Especial de Saude Publica*.

Included are data on the incidence and mass treatment of intestinal parasitism in the valleys of the Amazon and Rio Doce Rivers, experiences with DDT and pyrethrum in the control of *Anopheles darlingi*, and a report on the construction of municipal water supplies in the area of the Rio Doce. Also included are a number of keys to the identification of Brazilian anophelines.

The Servico Especial de Saude Publica was created by an agreement between Brazil and the United States, represented respectively by the Ministry of Education and Health and the Institute of Inter-American Affairs. Operations have been continuous since 1942 with particular emphasis on public health practices in the more remote regions of Brazil.

100 YEARS OF PIONEERING

The Community Service Society of New York completes its first century in 1948. By way of celebration it is holding a series of symposia on "The Family in Tomorrow's World." Symposium II on March 17 and 18 concerned itself with "Health and Family Life." Among the speakers were Martha M. Eliot, M.D., President of the American Public Health Association, Professor C.-E. A. Winslow, Editor of the *Journal*, Hugh Leavell, M.D., of the Harvard School of Public Health, W. R. Aykroyd, M.D., of the United Nations Food and Agriculture Organization, and Bailey B. Burritt, Executive Director of the National Health Council, who for 30 years was General Director of the Community Service Society.

The memorial volume published in connection with the centenary celebration is a handsome book entitled *Frontiers in Human Welfare*. It is a thrilling story of the movements this agency, one of the oldest in New York City, pioneered. They are large in number and varied in interest—tenement house reform, milk inspection, visiting nurse

service, social service education, case work standards, nutrition service, old age care, fresh air camps, and a multitude of others.

For information about the published proceedings of the symposia and about *Frontiers* write Community Service Society, 105 E. 22nd St., New York.

WILL DALLAS LEAD THE WAY?

The following editorial appeared in the *Dallas Morning News* for February 23. Is this a harbinger of local government organization in which consolidated health units will lead the way? Whether a flash in the pan or the beginning of a trend, it deserves the consideration of every public official—health and otherwise.

One-fourth of the nation's population is without adequate health service, Dr. Haven Emerson, member of the American Public Health Association, says. He blames lack of funds. There aren't enough funds for all the departments, but the big trouble is too many departments.

The forty-eight states have some 18,000 local health units. That figures out an average of about six departments per county. Dr. Emerson, recognizing the inefficiency in this multiplicity, says 1,200 departments can do the job, or an average of about one health department for every three counties.

Drop Dr. Emerson's criticism right in the middle of Dallas County, and it is apt. We have twice as many health departments as we need. To go further, we have twice as many tax offices and policing agencies as we need. To go further, Texas has twice as many counties as it needs.

Until there is a sensible merger of these services, they are never going to be what they ought to be. As long as we have a county tax office that is king bee in its own sphere and a city tax office in its sphere, the tax payer is going to suffer in his sphere.

Unified control, uniform regulations and enforcement, permanence of policy, and tenure for employees would give Dallas County a public health service that would be the envy of the state.

The day will come, of course, when not only city and county services are consolidated, but the consolidation of services of several contiguous counties will be effectuated. A

boundary will be meaningless when urban centers run into other urban centers. In the meantime, merging Dallas's two health departments is a sensible step toward the efficiency the tax payer deserves.

PIERRE THE PELICAN SERIES

The Louisiana Society for Mental Health, Hibernia Building, New Orleans 12, has produced a series of pamphlets which is being distributed to the mothers of new-born babies, one pamphlet a month for twelve months. These pamphlets are designed especially for the parents of first-born children and are unique because of the simplicity and highly focused interest.

According to Lloyd W. Rowland, Ph.D., the Director of the Society, the reading level is the sixth grade and several unique educational devices have been included. The series has been prepared for "a highly motivated group" and the conversations have been put into a little character invented for the purpose—Pierre the Pelican. He carries the discussion through and gives continuity to the pamphlets and succeeds rather well in keeping the discussion from becoming long-haired. Quiz forms have been cleverly used at the end of each pamphlet.

The series is already being used in West Virginia and certainly the idea will have appeal elsewhere. Among those who have been consulted with reference to the series are Dr. C. Anderson Aldrich, Professor of Pediatrics of the Mayo Foundation; Dr. Milton J. E. Senn, Associate Professor of Pediatrics in Psychiatry at Cornell University Medical College, and Dr. Robert L. Sutherland, Director of the Hogg Foundation for Mental Hygiene at the University of Texas. Specialists from Ohio State University have been used to adjust the language to the proper level. It is gratifying to see an unusual piece of work so well done. It is worth the attention of other state departments of health and of mental hygiene.

FOOD HANDLERS' SCHOOLS

Food Handlers' Schools in Hawaii describes the preparation and actual presentation of a course of instruction for food handlers. Suggestions are given on such subjects as selecting the time of day for classes, location of the school, size of class, extent of records, and literature to be distributed. Discussed also are publicity, program content and methods of presentation, illustrations of charts used, and photographs of laboratory preparations demonstrated as part of the course. This report, prepared by B. J. McMorrow and F. A. Schramm, appears as *Supplement No. 199* to Public Health Reports of the U. S. Public Health Service.

PTA FOLLOWS THROUGH

The April *National Congress Bulletin* of the National Congress of Parents and Teachers, in an open letter to its local presidents from its national president, Mrs. L. W. Hughes, brings its members up to date on the Local Health Services Bill (S. 2189, H.R. 5644, H.R. 5678) sponsored by PTA. Mrs. Hughes summarizes the action of her agency's February Health Conference and suggests how each local chapter may stimulate community health planning. The same issue carries a digest of the Local Health Services bill by PTA's legislative chairman, Mrs. Stanley G. Cook.

ANNUAL REPORTS

Twenty-five Years of Public Health in New Mexico, the report of the first quarter century of the New Mexico's State Health Department, has just been published for the period 1919-1944.

It will be remembered that New Mexico is the only state with a mandatory health district law grouping the state's 31 counties into 10 health districts whose health departments are operated by local boards of health with the coöperation and assistance of the State Health Department. The events

that led up to this mandatory law passed in 1935 can be traced in this 25 year report. In 1921, for example, 5 counties had full-time county health officers, in 1922 three more were added, in 1924 two more. But in 1926 two fell by the wayside and in 1927 another. The doldrums of the early 30's gave rise in 1932 to the first recommendation to restrict the state for health purposes.

In the meantime recurring frequently in the various biennium reports are such comments as "Our record in respect to diphtheria is not one of which we are proud" (1921-1922); "this biennium also witnessed typhoid outbreaks" (1923-1924); "occasional cases of malaria have appeared in two new areas of the state" (1925-1926); "the infant mortality rate is the highest in the United States" (1931-1932); "New Mexico has the highest infant death rate in the United States" (1937-1938).

A final chapter on the present health status of New Mexico points out that the infant death rate is still the highest among the 48 states; that the tuberculosis death rate is among the highest; the death rate from infectious and contagious diseases is three times that of the country as a whole. More than two-thirds of its dwellings have unsatisfactory sewer connections compared to 35 per cent in the entire country. This document should be the bible of things done and still to be done for citizen groups who want to start a movement for better health protective services.

Our hats off to the State Health Officer, James R. Scott, M.D., and his staff for telling the bad news as well as the good. Only in this way can come to pass the hope expressed "that the report on fifty years of public health may delineate the progress toward a more satisfactory status in the field of public health."

"Balance Sheet 1947" is the sub-title of the December, 1947. *Oakland's*

Health. This is the annual summary of the Oakland, Calif., City Department of Public Health. It has a Credit and a Debit section as well as A Job for the New Year—an interesting idea for a brief annual report.

The *1947 Annual Report of the National Social Welfare Assembly* is a brief summary of the activities and developments of the second year of this organization.

The *1947 Annual Report of the Social Security Administration* is the first report since its establishment in July, 1946, under the federal executive reorganization. It includes the report of the Bureau of Old Age and Survivor's Insurance, of Employment Security, and of the Children's Bureau. Along with

the annual report of its companion agencies, the U. S. Public Health Service and the Office of Education, it is an analysis of the social welfare services of the federal government.

Has the Tide Turned? is the 34th annual report (for the year 1947) of the American Social Hygiene Association. It is a good brief and graphic description of the Association's current activities. The title suggests that in 1947 some of the ground lost during the post-war years 1945 and 1946, when the country experienced a spectacular rise in reported cases of syphilis and gonorrhea, was regained. The last year also saw the development of the extensive worldwide service in stimulating social hygiene activities.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Recent Advances in Public Health
—By J. L. Burn, M.D., D.Hy., D.P.H.
London: J. & A. Churchill Ltd., 1947.
409 pp. Price, \$5.00.

This book is a condensation of the enormous social advances of modern Britain in public health. It does not attempt to present a complete picture of public health progress. While including a broad coverage, even Municipal Foot Health Service and Welfare of the Aged, greatest emphasis is on maternal and child problems. There are detailed accounts of mental health services, the care of unmarried mothers, the handicapped child, including blind, color blind, squint, deaf, speech defects, tonsils, and asthmatic, the diabetic, the rheumatic, and the child with cerebral palsy. The author assumes a broad fundamental background and the book is for the professional public health worker. There are detailed accounts of diphtheria immunization procedures and of tuberculosis mass x-rays. The "social" permeation is seen even in venereal disease control, which emphasizes contact investigation and followup rather than penicillin treatment of syphilis. Reliance on health education, of persuasion rather than compulsion, will make every American health worker appreciate the similarity of our democratic processes.

The presentation includes many classic discoveries and thumb-nail descriptions, such as the famous M'Gonigle report on housing and health, showing that the higher rents of rehousing may deplete nutrition and increase death rates, the superb contributions of Pickles to rural epidemiology, and the unique

Pioneer Health Center at Peckham. One tours the famous Papworth Village Settlement where the tuberculous work in a fashion which would make most American phthisiologists shudder and where, without benefit of BCG, the children of the tuberculous enjoy a remarkable healthy life without being removed from the tuberculous family. There is a summary of the remarkable experience at North and South Shields on the caries-detering effect of optimal fluorine in the water.

The index is very poor, but this is a book to be read in its entirety. This is very easy, for illustrations are profuse and smart, and the phraseology and expressions are just enough different to be very lively. For instance in the section on "Defective Colour Vision," the author remarks on resultant social difficulties, such as "the man who wore a red tie by mistake at his mother-in-law's funeral." In the description of the Recuperation Centres for the care of exhausted mothers we read: "As one mother put it: 'I should never have had the pluck to have all my teeth out at home.'" Even the one gross error in fact arouses only an indulgent smile. In relating the American experience in smoke control, he discusses the experience of St. Louis, Minnesota—"St. Louis was the dirtiest city in Minnesota." Although most references are to British experiences, the "U. S. A." comes in for many, as do Canada, the Continent, Scandinavia, and the U.S.S.R. Each chapter begins with a pungent text and closes with excellent selected references and valuable further reading suggestions.

This is a book which every public health worker in the United States and Canada can read with real profit and genuine pleasure. Burn will personally guide you on a trip through Britain and will frequently surprise you with penetrating observations on your own practices. CHARLES EDWARD SMITH

Atlas of Bacteriology—By R. Cranston Low, M.D., and T. C. Dodds. Baltimore: Williams & Wilkins, 1947. 168 pp. 168 illus. Price, \$8.50.

The purpose of this atlas is to afford students accurate pictures to refer to in illustration of lectures, practical classes, and textbooks.

The pictures are made from color photographs for the most part, giving the source of the material, how it is stained, what it shows, and the magnification. The characters of the microorganisms are not given.

The pictures substantiate the great trouble the authors have taken to insure accuracy and the coöperation and trouble taken by the original publishers (E & S Livingstone, Edinburgh) in meeting the exacting conditions required. This is undoubtedly the best atlas this reviewer has seen, and the selection of material is very good. It will be valuable to anyone who requires an atlas.

The value of the book would have been enhanced by the inclusion of references to the technique of the staining methods used. Minor criticism may be made of three items: the method illustrated on page 63 is Dorner's method and not Fleming's; the gonococcus colony on page 38 is misleading as it must be an old colony rather than a young one; the color of the pigment of "*B. pyocyaneus*" on page 21 is much too blue. E. G. D. MURRAY

The Cerebral Palsied Child and His Care in the Home—By Viola E. Cardwell, R.N. New York: Association

for the Aid of Crippled Children, 1947. 196 pp. Price, \$1.00.

This book is a welcome addition to the literature on cerebral palsy as there is still a paucity of written material on this subject. It is a carefully compiled book, written for the Association for the Aid of Crippled Children.

Although it was primarily intended to be used in staff education for nurses engaged in orthopedic public health nursing, it contains valuable information for physicians, technicians, and others who are beginning to become interested in this highly specialized field. In fact, the layman who has had to cope with the problem in his home will be able to comprehend most of the material and find helpful suggestions in the text.

The book is a practical one as the author has drawn from recognized authorities and workers in the field. Discussed in the first few chapters are the etiologic factors, pathology, prognosis for rehabilitation, and the various clinical forms of cerebral palsy which have been recognized to date. The remaining chapters deal with such important topics as mental hygiene, education, types of treatment, and the place of each in the overall program for the cerebral palsied child. The text also takes up the necessity of recreation and vocational guidance for those not too severely handicapped.

The author also pays tribute to the various societies founded by laymen, particularly those in and around New York City, which have demonstrated to physicians, educators, and technicians the need for programs of specialized care in dealing with this highly technical problem. These few interested parents have aroused long delayed interest in the cerebral palsied child and his many problems.

Replete with pictures and drawings of special equipment needed in the care of this type of handicapped child, it is

which publishes it is made up of 46 learned societies, including the American Public Health Association.

In the 1947 edition of more than 1,100 pages, 146 authors discuss 27 subjects under 7 main headings. The volume is "an elbow companion for everyone interested in contemporary events." It is source material for an appraisal of the age in which we live and an instrument for keeping informed on America, which is the fundamental duty of citizenship.

The article on Public Health, one of seven included under the Medical Sciences under the larger title of "Science: Application and Principles," is written by William R. Willard, M.D., of the Yale University School of Medicine.

A valuable feature of the *Year Book* is a list of periodicals and of cognate societies and research institutions in each of the seven main subjects of the volume.

MARTHA LUGINBUHL

Planning for the Care of the Chronically Ill in New York State—Legislative Document (1946) No. 66A. P.P. 131—By New York State Health Preparedness Commission. Albany: Williams Press, 1946. 85 pp.

This Legislative Commission with many years of study of health and welfare problems behind it has prepared a document which, while directed primarily to conditions in New York State, should serve as a useful guide to procedure and planning in other states.

The Commission was buttressed by strong advisory committees on Planning, Medical Education and Research and Nursing Care. The Commissioners of the State Departments of Health and of Social Welfare were ex-officio members of the Commission.

The report is well organized and readable. It is replete with charts, graphs, and tables. The summary of licensure of nursing homes in 20 states, together

with detailed reporting on planning for the care of the chronically ill in other states (Connecticut, Illinois, Indiana, Massachusetts, and New Jersey) provide useful information.

Under the following headings the findings and conclusions are stated: Convalescent Care, Medical Domiciliary Care, Nursing Homes, Voluntary Homes for the aged.

This report will be helpful to all those who are now facing the problem of providing for the care of the chronically ill in their own homes, hospitals, nursing homes, and elsewhere.

ELLEN C. POTTER

Advances in Internal Medicine. Volume II—Edited by William Dock and I. Snapper. New York: Interscience, 1947. 642 pp. Price \$9.50.

Those who expect this volume to be a year book of internal medicine will be disappointed. The volume consists of thirteen articles, of the review type, dealing with subjects in which advances are being made. The topics include electrocardiography, circulation of blood, penicillin treatment, the Rh antigen, megaloblastic anemias, and nutrition, as well as fields of interest to the internist. The latter include angiography, surgery for hypertension, and lung disease, insect control, and problems related to aviation and deep sea diving.

Well selected, the articles are comprehensive; they are thoroughly done by experts. The volume will be of interest to internists, those who wish to become internists, and those who want to know how and where internal medicine is advancing.

W. A. DAVIS

Food, Nutrition, and Health—By E. V. McCollum, Ph.D., Sc.D., and J. Ernestine Becker, M.A. (6th ed.) Baltimore: Johns Hopkins University, 1947. 146 pp. Price, \$2.00.

This is the sixth edition of a little book that has been well received in the

past and which serves a useful rôle in informing health personnel and interested laymen in modern nutrition. The current edition has been mostly rewritten and includes an account of many recent findings in nutrition. It is by no means a textbook or reference book in nutrition, but it is not intended as such. There are no references and practically no discussion. It is well written and in non-technical language.

In addition to the usual sections on various nutrients there are chapters on certain foodstuffs, diet in relation to anemia, pregnancy, and lactation, weight control, preventive dentistry, etc., and suggestions on conserving nutrients in foods and menu planning. Many of these sections are very brief, amounting to only one or two pages. The reviewer questions the advisability of including in a book of this type any reference to such vague entities as vitamins B₃, B₁, B₅, B₇, etc.

On pages 42 and 43 is a table entitled "Summary of the Vitamins of Known Significance to Humans," which includes vitamin E, pyridoxine, biotin, and vitamin P which, so far as the reviewer knows, have no established rôle in human nutrition. A paragraph on fat and water appears to have been mislaid in the chapter on mineral elements.

There is a need for a book such as this one and it is well written. Public health would be improved if more public health personnel knew what was between the covers of this little book.

FREDRICK J. STARE

American Foundations and Their Fields—Part I—*Edited by William B. Cherin. New York: Raymond Rich and William Cherin Associates, 1947. 58 pp. Price, \$6.00 (4 parts).*

Public health workers will have reason to be grateful to the authors for an up-to-date review of American Foundations and their programs. This represents a sequence of publications

originally presented by the Twentieth Century Fund and more recently by Raymond Rich Associates.

The survey has been broken down into four parts. This volume includes the Foundations' fiscal years ending February 28 to July 1, 1947. Each Foundation has been asked to provide information relating to the date of its establishment, the source of its funds, its purposes, the methods of operation, the direct activities, the financial data, the availability of reports, and the list of officers. It is notable that a considerable number of these agencies which enjoy tax exemption publish no reports and some refuse all information. It would appear to the reviewer that such information as is here presented should be mandatory for all foundations as a condition of the benefits which they enjoy.

REGINALD M. ATWATER

Food Regulation and Compliance. Volume II—*By Arthur D. Herrick. New York: Revere Publishing Co. 655 pp. Price, \$10.00.*

In volume I of this work the author, after briefly recounting the early history of legislation for food control, presented a comprehensive discussion of regulation through labeling requirements. In the first volume as in this second book, the discussion is chiefly limited to the Federal Food, Drug and Cosmetic Act. Some few other topics are given mention, such as the Federal Meat Inspection law and the problem of second-hand and used containers.

This second volume deals primarily with the problems of adulteration and contamination of foods, of control of permitted colors and the methods of enforcement and prosecution, all from the standpoint of the Federal Food, Drug and Cosmetic Act. There is a well written chapter on Insanitary Premises and Processing which will be of special interest to the public health official concerned with food control. In

this part of the book the author shows how the former limited federal control over food products solely by means of chemical and bacteriological tests was weak and ineffective, and now through the new sections of the law giving the Food and Drug Administration authority to inspect plants and provide sanitary standards for production and distribution the federal control has been greatly expanded and enhanced. However, these sections of the federal law become operative (giving authority for plant inspections and setting of sanitary standards) only after it has been established "that proper sanitation is so lacking that the food (a) may become contaminated with filth, or (b) may have been rendered injurious to health."

The book deals fully with the administrative practices and enforcement methods of the U. S. Food and Drug Administration. It is a volume that will be especially valuable to health officials who come in contact with the federal food control activities. The book contains the organization of the U. S. Food and Drug Administration and, in an appendix, provisions of the Federal Food, Drug and Cosmetic Act relating to foods.

SOL PINCUS

Fundamentals of Immunology—
By William C. Boyd, Ph.D. (2nd ed.)
New York: Interscience Publishers,
1947. 503 pp. Price, \$6.00.

The author addresses himself "mainly to students and research workers." At the end of each of the eleven chapters the pertinent material is presented in condensed form as a summary. These brief accounts when read consecutively without reference to the text constitute an excellent picture of the current views of the principles of immunology.

In the full text the author has taken care to introduce each new concept with sufficient elementary explanation to permit the student new to the subject to grasp the ideas. However, the elemen-

tary material is usually brief enough to avoid interference with the use of the text by research workers who wish to find more advanced material.

The eleven chapters include discussions of "cell antigens," "blood groups," "anaphylaxis and allergy," allergy and immunity as regards bacteria, viruses, and parasites, and "laboratory and clinical technic." The subject of skin tests for susceptibility and immunity is treated rather briefly in an appendix to one of the chapters. The bibliographies at the end of the chapters are extensive.

This book is well written. It should accomplish the author's objective of presenting the fundamentals of immunology to students and research workers.

J. C. SNYDER

Medicine for Moderns—*By Frank G. Slaughter, M.D. New York: Julian Messner, 1947. 246 pp. Price, \$3.50.*

Medicine for Moderns is a frank, easily read discussion of the concepts, mechanisms, therapeutic approaches, and hopes of psychosomatic medicine. Written in popular style for educated laymen, it succeeds in avoiding both the extreme sensationalism so common in books of this nature, and the insult of "talking down." Dr. Slaughter's intense enthusiasm, as a convert trained primarily in surgery, leads him into some wishful thinking in relation to the curative and preventive values of personality psychometric testing. The essentiality of individualization warrants somewhat greater emphasis. However, the material is sound and well presented.

Following a brief description of the anatomy and physiology of the autonomic nervous system, the author takes up the more obvious of the psychogenic illnesses: peptic ulcer, spastic colitis, hypertensive disease, asthma, and the like. There is an obvious appeal for popularity in the emphasis placed upon the psychogenic factors responsible for

impotence and frigidity. One misses accentuation of the important fact that all these disorders are characteristically derived from varied and multiple etiologic factors, and that continued anxiety is but one of several influences.

The book can be recommended as background reading for the laity, and may also be of value to those medical professionals who are asymmetrically organicists, insisting that that which cannot be seen does not exist.

EDWARD J. STIEGLITZ

Sports for the Handicapped—By George T. Stafford. (2nd ed.) New York: Prentice-Hall, 1947. 334 pp. Price, \$5.00.

There are few more satisfying fields of endeavor within physical and health education than working with handicapped students or with disabled patients. Stafford, in this exceedingly helpful second edition has pointed the way to a continuous betterment of programs which deal with the atypical. His book will be useful wherever people are concerned about the organic, psychological, and social rehabilitation and compensations of those who must seek to live most with what they have.

Stafford has long believed, and demonstrated, that sports can be adapted to the disabled. Prior to the war physical education departments in colleges and in some high schools were moving in this direction, but not as rapidly as the need demanded. The human wreckage produced by the war gave impetus to experimentation and, through the efforts of people like Stafford, Daniels, Esslinger, Kelly, Elkins and others, a full measure of good was done the disabled by ingeniously adapting sports or creating new ones for these very special purposes.

This second edition presents excellent material for use with the personality or psychologically handicapped, the amputee, the deaf, the paralyzed, those with

faulty body mechanics, malnutrition, circulatory misbalances, and spinal deviations. There are useful suggestions throughout for physicians and physical educationists. It should be read, and used widely. DELBERT OBERTEUFFER

Artificial Pneumothorax in Pulmonary Tuberculosis—By T. G. Heaton, M.B. (2nd ed.) New York: Macmillan, 1947. 292 pp. Price, \$4.50.

The revised edition (1947) of this book presents a concise and selective report of an important part of a system of collapse therapy in phthisiotherapy. The contents are contained in 16 chapters carefully arranged and chosen to lend a proper continuity to the subject. The literature on artificial pneumothorax is enormous and the author's selection and classification of authoritative references represent careful study and timely abstracts. The statistical data are reduced to a minimum consistent with satisfactory explanations of the text. The departure from complicated tables is welcomed by the busy practitioner.

The author's excellent training and experience permit a crystallizing of thought on many controversial points, and his own expressed opinions reflect the good judgment of the careful clinician.

The public health physician interested in tuberculosis prevention and control will find in this book a ready "up to the minute" reference on the latest scientific thoughts about the treatment of pulmonary tuberculosis by pneumothorax. It will be particularly welcome in the tuberculosis division or clinics of the health department, and more especially if such outpatient department service includes post-sanatorium pneumothorax supervision and refill treatments.

It would be unusual indeed if every reader of this book would agree with the author on all debatable points. The purpose, however, is served in presenting

accurate thought-provoking material to serve either as a supplement to knowledge of the subject already gained or to stimulate the reader to obtain further detailed knowledge of pneumothorax therapy beyond the limitations of the book itself.

The reviewer believes that this stimulating book from Canada is a real contribution to the field of tuberculosis therapy and should be read, understood, and made available for reference by all physicians actively engaged in the practice of tuberculosis or in the general field of pulmonary diseases.

JOHN A. CARSWEL

Physiology and Pathology of the New-born—*Compiled by A. N. Antonov, M.D. Monographs of the Society for Research in Child Development. Vol. X Serial No. 41, 1945, No. 2. Washington, D. C.: Society for Research in Child Development, National Research Council, 1947. 217 pp.*

This volume is a publication of the Society for Research in Child Development of the National Research Council. It is a bibliography or index of material on the physiology and pathology of the new-born for the period 1930-1940. A. N. Antonov, M.D., of Leningrad, has made a valuable contribution by compiling this extensive bibliography concerning scientific articles from all centers of the world. At even a glance the reader is impressed with the international interest in the physiology and pathology of new-born infants.

The table of contents shows 38 sections, with such titles as Fetus, The Influence of Pregnancy and Labor on the New-born, Anthropometric Data, Metabolism of the New-born, Congenital Abnormalities and Malformations, Birth Injuries, The Respiratory System, Other Systems, and Infectious Diseases. The book is valuable as reference material.

The large number of scientific arti-

cles on physiology and pathology of the new-born is truly impressive and shows the vast amount of work that was done between 1930 and 1940 preparing the way for further scientific knowledge and its application today.

MARTHA L. CLIFFORD

Industrial Environment and Its Control—*By J. M. Dallavalle. New York: Pitman Publishing Company, 1948. 225 pp. Price, \$4.50.*

This is an authoritative work on industrial hygiene presenting the engineering phases of environmental control in the prevention of occupational hazards, and it is written principally for engineers. However, this book should be read not only by industrial hygiene engineers but also by industrial physicians who need to know the engineering phases of industrial health service and the extent to which the medical service must be backed up by competent engineering if satisfactory results are to be obtained.

The book has a notable preface which clearly states both the aims and scopes of environmental control as well as their limitations. The author discusses the influence of atmosphere, the estimation of atmospheric qualities, and the variations from the normal that constitute health hazards. Vibration, fatigue, illumination, and radiant energy are amply presented.

There is a discussion of the methods of ventilation and the design and construction of ventilating systems, exhaust systems, and dust collection systems, together with the control of bacterial infections.

Finally, there is an appendix which covers briefly regulations, standards, and desirable practices, including brief statements on medical service, first aid, physical examinations, and record keeping.

The author is to be commended on a most worth while book. 'A. J. LANZA

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- ASEPTIC TREATMENT OF WOUNDS.** Carl W. Walter, M.D. New York: Macmillan, 1948. 372 pp. Price, \$9.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, Ph.D.

"More About Our Ignorance"—Would you like to see a paper that, by example, tells you how to prepare a readable report in addition to passing on some information to you? Then search out this particular British health journal. The paper is about the much written up colds research they have been carrying on with human volunteers.

ANDREWS, C. H. The Common Cold. *M. Officer* 79, 6:55 (Feb. 7), 1948.

Incidental Intelligence—Butylacetanilide repels ticks for 10 days and works against chiggers, too—just in case you wish to protect yourself against either of these pests. You dip exposed clothing in a solution, it seems.

BRENNAN, J. M. Field Tests with Tick Re-

pellants. *Pub. Health Rep.* 63, 11:339 (Mar. 12), 1948.

Largely Undeserved Praise—If you would like to enjoy a mild case of swelled head, read this Britisher's account of his visit to America last fall. He saw everything that was good and nothing that was bad, apparently. I cannot forego just one quote: "Almoning, or as it is called in America, medical social work is developing apace, and a chair in this subject has been established at the University of Yale."

DALEY, A. Impressions of America. *Public Health.* 61, 5:77 (Feb.), 1948.

Muscles and Emotions—Fitness seems to be the ability to perform the

tasks of daily living without undue fatigue, and the qualities making this possible are those of the total personality for physical and psychologic factors cannot be disassociated. This definition works pretty well whether applied to athletes, laborers, sedentary workers, the handicapped or the aged. Measuring fitness is a complicated procedure not lightly to be attempted.

DARLING, R. C., *et al.* Physical Fitness. J. A. M. A. 136, 11:764 (Mar. 13), 1948.

Thirty Million Hungry Children—Says our President—back from a tour of Europe—the greatest need of children everywhere over there is MILK and more MILK. Someone should tell this to our statesmen who refuse us the margarine that would release for these children some of the surplus milk now being churned into unneeded butter.

ELIOT, M. M. The Need of the Children. Survey Graphic. 37, 3:140 (Mar.), 1948.

Children First in Every Country—We have widespread evidence in Europe, this British reporter writes, of the unrest, bitterness, disease, and destitution existing among those who suffered as children in the early war years and are now approaching manhood. But the record is not all black, he concludes.

ELLIS, R. W. B. Effects of War on Child Health. Brit. M. J. 4544:239 (Feb. 7), 1948.

Of Human Interest—There isn't much here but what there is, is 22 Karat. Good public speakers never forget, the professor says, that "people are interested in people." Send out speakers, he advises, who can make people laugh, but he doesn't tell you where to get them.

HANNA, M. Good Public Relations Requires Good Public Speakers. Am. J. Nurs. 48, 3:163 (Mar.), 1948.

This Hits Babies Hardest—Crowd-

ing, flies, improper excreta disposal, and bad personal hygiene all were associated with diarrheal disorders caused by *Shigella* infection. But water, milk and other foods did not seem to be implicated.

HARDY, A. V. and WATT, J. Studies of the Acute Diarrheal Diseases. Pub. Health Rep. 63, 12:363 (Mar. 19), 1948.

Silver-Lining Department—Here is a striking bit of economics passed along to you for what it is worth; the average stay in hospital is now a third of what it was three decades ago, and it costs twice as much per day. An illness that used to cost the victim \$150 now costs him \$100 for his hospitalization.

MACLEAN, B. C. The Hospital as a Community Health Agency. Pub. Health Nurs. 40, 3:115 (Mar.), 1948.

After Twenty Years—Physical defects discovered in New York State school children dropped in incidence, during the past two decades—except dental defects. They increased.

MAXWELL, C. H., and BROWN, W. P. The Age-Incidence of Defects in School Children, Their Changing Health Status. J. Sch. Health 18, 3:65 (Mar.), 1948.

Thought-for-the-Month — Trickle down from on high comes the rain of life-giving subsidies—from federal treasuries to states and from states to the communities—to support competent local health services. What is needed in return is a welling-up from below—from local workers to state commissioners to federal officers—of grassroots advice to avoid arbitrary and bureaucratic rulings that may lower the effectiveness of this productive partnership.

MERRILL, M. H. Federal-State-Local Relationships in the Financing of Local Health Services. Pub. Health Rep. 63, 8:244 (Feb. 20), 1948.

In Union There is You-Know-What—America's professional men and

women are sharing neither the profits of business nor the bargaining power of labor, this authority says. The A.N.A. is demonstrating how better incomes can be secured without sacrificing professional ethics or resorting to demeaning tactics. Is this assertion of any interest to you?

NORTHROP, H. R. *Collective Bargaining and the Professions*. Am. J. Nurs. 48, 3:141 (Mar.), 1948.

Warning Against Clock-Training

—Even though you are an engineer or a technician or a statistician, and even though you have no babies of your own, you should read this paper. As the first discussant says, "It shows that material

can be presented in simple language and yet be of the highest scientific value." And that, Brother, is something you and every one of us jargoneers needs to learn.

SPOCK, B. *Common Behavior Disturbances in the First Two Years of Life*. J.A.M.A. 136, 12:811 (Mar. 20), 1948.

To Measure Under-Reporting —
Promising to be the first of a series of discussions on the adequacy of local morbidity reporting practices and ways to increase completeness, this paper gives some hint of the present weakness and variables.

WEST, M. D. *Morbidity Reporting in Local Areas*. Pub. Health Rep. 63, 11:329 (Mar 12), 1948.

The Committee on Administrative Practice will plan for occasions during the 76th Annual Meeting of the Association in Boston, November 8-12, when Dr. Buck's friends will have an opportunity to greet him.

Succeeding Dr. Buck as the Association's Field Director is Roscoe P. Kandle, M.D., M.P.H., who was associated with Dr. Buck during 1946 and who left the Association staff to become Director of the Bureau of Preventable Diseases with the New Jersey State Department of Health in Trenton. Dr. Kandle is well equipped to carry on. With him is associated Robert E. Rothermel, M.D., M.P.H., as Assistant Field Director. Both Dr. Kandle and Dr. Rothermel are currently engaged in a survey of the State of Pennsylvania at the request of the Pennsylvania State Department of Health and Governor Duff.

GIFT TO COMMITTEE ON CHILD HEALTH

At the first meeting of the Associa-

tion's new Committee on Child Health in New York on March 20, announcement was made of a gift of \$300.00 from the residual funds of the Association of Women in Public Health.

The Association of Women in Public Health, first organized in 1920, voted to disband late in 1947 and to join forces fully with the American Public Health Association. Its Treasurer, Dr. Susan M. Coffin, referred to the gift as a "humble dowry" presented at the time of what Dr. C.-E. A. Winslow termed her Association's "marriage with the American Public Health Association."

The new Committee on Child Health at its first meeting explored areas of co-operation with such agencies as the American Academy of Pediatrics, the Children's Bureau, the National Institute of Health, school health organizations, and the Association's Standing Committees on Professional Education, Research and Standards, and Administrative Practice.

offices and laboratory. Salary for man with degree in public health \$7,500 plus 8¢ per mile travel. Write City-County Health Department, Safety Building, Eau Claire, Wis.

NEWS FROM THE FIELD

WORLD HEALTH ORGANIZATION

"Ever since it was proposed at the San Francisco Conference of 1945 and endorsed by the State Department, this country has taken an active part in the creation of a World Health Organization. We were represented at a preliminary health conference held in Paris in 1946 and later in the same year at the definitive International Health Conference which was held in this city by the representatives of sixty-eight nations and which decided that a World Health Organization was to be established as soon as twenty-six nations had signified their approval. Meanwhile an interim commission, with offices in Geneva and New York, has been demonstrating what such an organization can accomplish, one conspicuous example being the aid rendered in controlling a recent cholera epidemic in Egypt which threatened to involve the whole Near East. Last year the Senate passed a bill which would have made the United States a member of the World Health Organization and which was approved by the House Committee on Foreign Affairs.

"Despite this history, despite the support given to a World Health Organization by the American Public Health Association and virtually every public health authority, the Rules Committee of the House has seen fit to table the Senate's bill. No reason for an action which was taken behind closed doors. Twenty-two nations have already signed the covenant of the World Health Organization, and four more will do likewise in six or eight weeks. This means that an organization will be created, but that the United States will not be a member. The Rules Committee of the House owes the public an explanation.

If it has any good reason for failing to approve the action of the Senate that reason ought to be presented. This country has always been a leader in supporting international efforts to control the spread of disease. At a time when most of continental Europe is undernourished and tuberculosis and other infections are increasing the United States cannot afford to give up that leadership and assume the role of an indifferent observer."—*New York Times*, Mar. 20, 1948.

1948 NORTH CAROLINA WATER WORKS OPERATORS' SCHOOL

The 1948 North Carolina Water Works Operators' School will be held June 7-11 at the University of North Carolina. This school is sponsored by the North Carolina Water Works Operators' Association and the North Carolina Section of the American Water Works Association and is conducted co-operatively by the School of Public Health and the Institute of Government of the university.

Students will be divided into 4 groups according to background, training, and present interest. Instruction will be given in 20 subjects, many of them common to 2 or 3 groups. Not only will technical problems such as filtration, chlorination, corrosion, water quality, hydraulics, and others be discussed but also records, personnel, and legal problems.

As in former years, the school is open both to North Carolina water plant personnel and to residents of neighboring states.

The final schedule of instruction and other information may be secured from Assistant Director, Institute of Government, Chapel Hill, N. C.

THE RETIRING AND INCOMING SURGEONS GENERAL OF THE U. S. PUBLIC HEALTH SERVICE

THOMAS PARRAN, M.D., Surgeon General of the U. S. Public Health Service, 1936-1948

S. delegation.

Commissioned Officer in the U. S. Public Health Service, 1934; Health Officer, Queen Anne's County, Md., 1936-1937; Special Fellow, Memorial Hospital, New York, 1937-1939; Officer in Charge of the National Cancer Control Program of the National Cancer Institute, 1939-1942; Assignments with the Public Health Branch, Military Government, U. S. Army, for which he was awarded the Legion of Merit and American Typhus Medal, 1943-1945; Assistant Chief, National Cancer Institute, 1946-1947; Assistant Surgeon General and Director of the Cancer Institute, 1947; Member of the American Public Health Association since 1937.

SECOND N.T.A. RESOLUTION ON LOCAL HEALTH UNITS

The following resolution was passed by the Board of Directors of the National Tuberculosis Association at its meeting on March 19:

The National Tuberculosis Association re-emphasizes its policy that tuberculosis services, to be most effective, should be integrated with general community health facilities and to that end urges its state and local affiliates to work toward the establishment of adequately financed and adequately staffed local health services.

The National Tuberculosis Association endorses the principle enunciated by representatives of 65 national citizens' organizations in a meeting at Princeton, N.J., on September 10, 1947, to the effect that vigorous steps be taken to obtain complete coverage of all states and all communities by local full-time health units under competent professional direction.

The National Tuberculosis Association offers its coöperation to the National Health Council in this program.

The National Tuberculosis Association further endorses in principle the need for federal legislation and assistance to states to complete the coverage of their respective populations and areas with full-time local health units under professional direction.

An earlier resolution of the N.T.A. urged its state and local affiliates to co-operate in developing local official health services as a necessary prerequisite to effective local tuberculosis control activities.

INTERNATIONAL POLIOMYELITIS CONFERENCE

The First International Conference on Poliomyelitis in New York City, July 12-17, was announced briefly in the February *Journal* (p. 252).

More detailed plans are now available. Ten world medical and research authorities on poliomyelitis have been named presiding officers for the plenary sessions. These presiding officers and subjects include:

Oswaldo P. Campos, Clinical Orthopedic Surgeon, Hospital Jesus, Rio de Janeiro, Brazil, "The Importance of Poliomyelitis as a

World Problem"; Rustin McIntosh, Professor of Pediatrics, Columbia University, "Poliomyelitis: The Early Stage"; Robert Kno-Song Lim, Surgeon General, National Defense Medical Center, Shanghai, China, "The Management of Poliomyelitis: The Early Stage"; Arthur Steindler, Professor of Orthopedic Surgery, State University of Iowa, "Poliomyelitis: The Convalescent Stage"; Arvid Wallgren, Professor of Pediatrics, Royal Caroline Medical Institute, Stockholm, Sweden, "The Management of Poliomyelitis: The Convalescent Stage"; Carlos S. Ottolenghi, Docente Libre de Ortopedia, Buenos Aires, Argentina, "The Management of Poliomyelitis: The Late Stage"; James E. Paullin, Professor of Clinical Medicine, Emory University, "Bulbar Poliomyelitis"; Pierre L. LePine, Director of Laboratories, Pasteur Institute, Paris, "Immunology and Chemotherapy in Poliomyelitis"; Harry S. Mustard, Commissioner of Health, New York City, "The Public Health Aspects of Epidemic Poliomyelitis"; and Thomas Parran, Surgeon General, U. S. Public Health Service, "Poliomyelitis Throughout the World."

The Conference is being held under the auspices of the National Foundation for Infantile Paralysis with the coöperation of 23 United States government agencies and scientific societies, among them the American Public Health Association.

Conference headquarters have been set up in the Waldorf Astoria Hotel, New York City.

INSECT CONTROL IN RETROSPECT

This announcement will be too late to be of any great benefit to health workers in the field. However, it may tend to indicate trends which are taking place in insect control activities. Within almost a week, notices were received of two conferences for pest control operators; the first, that of the New York State Pest Control Association held at Cornell University, March 29-30, and second, that of the 12th Annual Purdue Pest Control Operators Conference held at Purdue University, April 5-9. Anyone who may be interested in programs or methods of organization should write

to Charles E. Palm, Entomology Department, Cornell University, Ithaca, N. Y., for the former, and to Professor J. J. Davis, Agricultural Hall, Purdue University, Lafayette, Ind., for the latter.

WATER EMERGENCY PUBLICITY MATERIAL

The Mathieson Alkali Works has prepared and distributed to state health officers in areas likely to be affected, a packet of material designed to advise the public of necessary emergency health measures in the event of floods. Included in the packet are releases for use in newspapers before, during, and after a flood. There are similar releases for radio broadcasts and a bulletin for posting in public places. Also included are recommendations concerning typhoid inoculations, treatment of water for drinking and cooking purposes, handling of contaminated food and food containers, disinfecting wells in flood areas, and clean-up of buildings after floods. A list of distributors handling chemicals which might be in demand during flood emergencies is also contained in the packet. For further information, write to Mathieson Alkali Works, Inc., 60 East 42 Street, New York 17, N. Y.

NEW ENGLAND MEETING

The annual Massachusetts Public Health Conference and the New England Health Institute will be held at the University of Massachusetts, at Amherst from June 16 to 18, 1948. Among the speakers at this three day session are:

Martha M. Eliot, M.D., President, A.P.H.A.
Leonard A. Scheele, M.D., Surgeon-General,
U.S.P.H.S.

Ira V. Hiscock, Sc.D., Professor of Public Health, Yale University

Hugh R. Leavell, M.D., Professor of Public Health Practice, Harvard University

V. A. Van Volkenburgh, M.D., Assistant Commissioner, New York State Department of Health

Charles F. Wilinsky, M.D., President-Elect A.P.H.A., will preside, and the New England state health commissioners will participate.

All members of the A.P.H.A. are invited and ample dormitory accommodations are available for all who wish to attend.

HEARING ON LOCAL HEALTH

SERVICES BILL

The Committee on Interstate and Foreign Commerce of the House of Representatives held a hearing on the Local Health Services Bill (H.R. 5644 and 5678) on April 8. Five members of the committee were present and heard testimony in favor of the bill from Mrs. L. W. Hughes, President of the National Congress of Parents and Teachers, James R. Miller, M.D., member of the Board of Trustees of the American Medical Association, Vlado A. Getting, M.D., President of the State and Territorial Health Officers Association and Haven Emerson, M.D.

The only opposing testimony, based on a fear of further federal centralization, was given by H. B. Anderson, Secretary of the Citizen's Medical Reference Bureau. He testified that he represented a membership of 1,000 members who had not previously been consulted, but would approve his action at a later date.

No hearing has yet been held on the identical Senate bill providing for federal grants-in-aid to state health departments earmarked specifically for the development of local health units on the basis of an overall state plan. The Chairman of the Senate Subcommittee on Health of the Committee on Labor and Welfare is Senator H. Alexander Smith of New Jersey.

PREVENTIVE MEDICINE TO THE FORE

At the Health and Family Life Symposium of the Community Service Society of New York, on March 18, Bailey

B. Burritt, the retired Director of the Society and Executive Director of the National Health Council, announced a project for the study of 200 families who live in one of New York City's neighborhoods to learn "what preventive and health maintenance services would be effective and practical." This service would utilize many of the techniques learned by the Peckham experiment in England. This experiment and its results were discussed at the same meeting by Dr. Innes Pearse, medical director.

Among other current activities, in exploring the possibilities of preventive medicine, is the University of Minnesota's project whereby 300 St. Paul and Minnesota volunteers in the prime of life are being examined periodically for 10 years by clinicians in order chiefly to note the factors that account for high blood pressure and for hardening of the arteries.

In New York City, the Health Commissioner, Harry S. Mustard, M.D., has appointed C. Ward Crampton, M.D., Chairman of an advisory committee on geriatrics. New York State has a joint legislative commission on problems of aging.

GRADUATE FELLOWSHIPS IN COMMUNITY NUTRITION AT THE UNIVERSITY OF TENNESSEE

The College of Home Economics of the University of Tennessee offers several one year graduate fellowships in Community Nutrition of \$1,200 and free tuition. The program, leading to the degree of Master of Science in Community Nutrition, includes three-quarters of work in residence at the university and one-quarter of supervised field work in a health agency. Candidates are trained for positions as nutritionists with health and welfare agencies.

Academic requirement for admission is a baccalaureate degree in home economics with a major in foods and nutrition, or its equivalent. Two years of

experience such as teaching, extension work, Farmers Home Agency work, hospital, or other food service or equivalent, are required. Interests and ability of the candidate are considered in accepting students for training.

Application blanks and further information may be obtained from the College of Home Economics, University of Tennessee, Knoxville.

FIRST NATIONAL SANITATION CLINIC

The first National Sanitation Clinic will be held at the University of Michigan, June 21-25 with the coöperation of the National Sanitation Foundation. Approximately 250 participants will divide themselves into 12 clinic groups for intensive deliberations on as many subjects related to food sanitation. In general each group will include 6 representatives from public health and 6 from industry, 2 co-chairmen, and from 2 to 5 consultants.

The stated purpose of the clinic is to discuss various phases of environmental sanitation control—with particular reference to foods—in an effort to arrive at a statement of principles, methods of procedure, equipment, etc., that are acceptable to public health officials and to industry. It is hoped that the agreements reached in this group may be approved by both public health officials and industry as reasonable goals and guides in food sanitation.

DR. HILLEBOE MAKES TRIP TO EUROPE

Herman E. Hilleboe, M. D., New York State Commissioner of Health, spent the last half of February on a trip to Europe, going first to Geneva, Switzerland, where he represented the United States in a four day discussion of worldwide tuberculosis control with members of the Expert Committee on Tuberculosis of the Interim Commission of the World Health Organization.

In addition, Dr. Hilleboe had a one day conference on tuberculosis control

with Rome public health physicians, made a three day study in Athens of the mass BCG vaccination program now in progress in Greece, and examined the research work currently being conducted by the State Serum Institute of Denmark in Copenhagen. There a coöperative research project was formulated to be carried on by the Serum Institute and the New York State Health Department's Division of Laboratories and Research.

TEXAS PUBLIC HEALTH ASSOCIATION

The Texas Public Health Association held its Annual Meeting in Houston February 22-25. This meeting was the largest ever held, with a total attendance of 575.

The out-of-state speakers included Pearl McIver, R.N., Martin A. Frobisher, Jr., D.Sc., Charles B. Frasher of the A.P.H.A. Merit System Service, Albert E. Bailey, Ph.D., James A. Doull, M.D., and Ira V. Hiscock, Sc.D., who led a panel on Public Health Administrative Practices.

The new officers of the Texas society are:

President—Austin E. Hill, M.D.

President-elect—W. R. Ross, M.D.

1st Vice-President—B. A. Young

2nd Vice-President—Belle Blackwell, R.N.

Executive Secretary—Earle W. Sudderth

A.P.H.A. UNDERTAKES STATE STUDY IN PENNSYLVANIA

Norris W. Vaux, M.D., Secretary of Health for Pennsylvania, has recently announced a survey of public health activities of Pennsylvania by the Committee on Administrative Practice of the American Public Health Association.

In commenting on this study, Dr. Vaux said:

The Pennsylvania Department of Health has had a long and honorable history. Its activities through the years have expanded with increasing knowledge in the techniques of preventive medicine and in the control of disease.

This expansion has been so rapid and diverse that there has been little opportunity to pause

and take stock, an essential practice for every organization that wants to know its present status and what future direction it should take.

With this thought in mind, Governor Duff, and I, believe that a thoroughgoing evaluation of the Commonwealth's public health administration which will measure structure and activities against currently accepted public health procedures and practice will be of value in strengthening the resources of the Department and in assuring it of an administrative structure soundly conceived and adequately operated.

With the Governor's approval, therefore, the Department of Health has requested the American Public Health Association through its Committee on Administrative Practice, which has conducted many local health studies, to survey the public health activities of Pennsylvania.

Important among the aspects of this survey will be the efficiency, extent, and effectiveness of (1) the state Department of Health; (2) local health services to communities; and (3) the relationship of the state voluntary health agencies to the state and local health services.

A representative committee of public minded and influential citizens, now being appointed by Governor Duff, will serve in an advisory capacity and Dr. Vaux has expressed the hope that this committee will be an effective instrument for implementing the survey's recommendations.

N.T.A. POLICY ON BCG VACCINATION

The Executive Committee of the American Trudeau Society, the medical section of the National Tuberculosis Association, recently adopted a statement of policy with respect to BCG vaccination against tuberculosis. Because such vaccination does not provide complete protection against tuberculosis its use for the general population is not recommended until further controlled studies are conducted.

The Society's recommended policy is for BCG vaccination of members of groups constantly exposed to tuberculosis if they have a negative reaction to the tuberculin test. The person with a positive reaction, indicating that he has had a primary tuberculosis infection

and his body has built up a degree of acquired immunity, probably does not benefit from BCG vaccination. For the present, therefore, BCG vaccination is recommended for doctors, medical students and nurses, hospital and laboratory personnel in contact with the tuberculosis bacillus, individuals unavoidably exposed to tuberculosis in the home, and patients and employees of mental hospitals, prisons, and other custodial institutions.

The Society warns against placing complete reliance on BCG even for these groups and points out that proper precautions should be taken to minimize or prevent "undue hazardous exposure of hospital patients and personnel and members of a household if an infectious patient is under treatment in the home."

PERSONNEL AND SERVICES OF LOCAL HEALTH UNITS

The U. S. Public Health Service through the Records and Reports Unit of the Bureau of State Services has just published a report of public health resources in local full-time health jurisdictions, including state districts. The number of personnel in 4 categories is analyzed according to whether they meet the minimum standards set up by the Subcommittee on Local Health Units in its report, *Local Health Units for the Nation*.

The report also gives detailed information on public health clinic service available in local jurisdictions receiving federal-state financial aid.

The report, prepared by Evelyn Flook and Arthur P. Gill, is available from the Bureau of State Services, U. S. Public Health Service, Washington 25, D. C.

FIELD TRAINING IN PUBLIC HEALTH ENGINEERING

The Michigan Department of Health announces summer field training opportunities to individuals desiring experience in public health engineering work.

The program will be similar to one conducted by the department last year.

Graduates or undergraduates of recognized professional schools with training in one of the branches of public health (engineering, dairy science, food technology, bacteriology, etc.) will be accepted. Undergraduates must have completed their junior year of study. Assignments will be to county health departments with special facilities for the training. Stipends of \$150 per month will be paid each candidate by the W. K. Kellogg Foundation. Veterans are entitled to the federal subsistence allowance while in training. Work will start about June 14 and continue to the middle of September.

Additional information can be obtained from John M. Hepler, Director, Bureau of Engineering, Michigan Department of Health, Lansing.

MARKLE FOUNDATION MEDICAL SCHOLARS

With the avowed purpose of relieving the current shortage of scientists equipped to carry on and teach research, the John and Mary R. Markle Foundation of New York recently announced a "Scholars in Medical Science" program. A total of \$400,000 has been allocated to support, for a 5 year period, 16 doctors carrying on research in a variety of medical subjects in 16 different universities.

100 YEARS OF A.A.A.S.

Planning has begun for the centenary celebration of the founding of the American Association for the Advancement of Science. Chairman of the Centennial Policy Committee is Dr. Harlow Shapley, Director of the Harvard Observatory. The keynote of the meeting, to be held in Washington, D. C., September 13-17, is "One World of Science." Preliminary plans call for technical symposia, 4 or 5 concurrently each morning, for free afternoons to visit the scientific and cultural institutions of Washington,

and for non-technical broad surveys of current progress in important fields of science for the evenings.

NATIONAL HEART INSTITUTE PROPOSED BY SENATE BILL

On February 25, Senators Ives, Bridges, Murray, and Pepper introduced the bi-partisan bill S2215, which would establish a National Heart Institute under the U. S. Public Health Service. It would provide greatly increased federal support of research in and control of cardiovascular diseases. The bill differs only slightly from the Keefe and Smathers bills introduced in the House in January.

U. S. PUBLIC HEALTH SERVICE 1949 BUDGET

The Washington Report on the Medical Sciences, a weekly newsletter concerning medical and public health matters, reports liberal grants to the U. S. Public Health Service by recent action of the House Appropriations Committee. The overall 1949 budget approved for the Service was \$173,230,500, an increase of 30 per cent over the previous year. Seventeen million dollars was approved for venereal disease control. Because the committee was impressed with the BCG studies conducted by the Public Health Service, over 9 million dollars was appropriated for tuberculosis control, two-thirds of which is for grants-in-aid to state and local health departments.

The National Institute of Health was granted its full request of \$13,570,000, plus an additional \$100,000 for peptic ulcer research. More than half of the institute's appropriation is for research grants to hospitals, clinics, universities, and other organizations.

The Institute's funds for cardiovascular studies were increased from half a million in 1948 to \$1,382,500 in the 1949 appropriation of the House. The cancer appropriation of \$14,000,000

was renewed plus an additional \$8,000,000 recommended for grants-in-aid for planning, land acquisition, and building of research centers.

A new item of a million and a half dollars was recommended for nation-wide demonstrations in schools of the effectiveness of sodium fluoride in preventing tooth decay.

PERSONALS

Central States

C. A. ABELE, formerly Director of the Country Dairy Inspection Section of the Chicago Health Department since 1940, has recently become Director of Public Health Research of the Diversy Corporation, also of Chicago. Mr. Abele organized and served for 20 years, the Bureau of Inspection for the Alabama State Department of Health. He is a referee on the Committee on Standard Methods for Dairy Products, A.P.H.A.

CORINNE EDDY, M.D.,[†] was appointed Health Officer for the DeWitt-Piatt County (Illinois) Health Department with offices in Clinton on January 1. Dr. Eddy was formerly Director of the City-County Health Department, Lincoln, Neb.

DONALD M. HARRIS, M.D.,* became Health Officer of the newly organized full-time Health Department of Gary, Ind., on February 1. According to the *Monthly Bulletin* of the Indiana State Board of Health he is "the first formally trained full-time health officer (local) in Indiana." He had previously served in local health units in Iowa, Michigan, and Nebraska.

J. P. OWENS, M.D., has been named to succeed E. H. SCHOENLING, M.D., as Hamilton County, Ohio, Health Commissioner. Dr. Owens has been a practising physician in Cincinnati chiefly interested in industrial medicine.

Eastern States

WENDELL R. AMES, M.D.,* former Health Commissioner of the Cattaraugus County, N. Y., Health Department, has been appointed Deputy Health Commissioner for Preventable Diseases, including tuberculosis control of the new Buffalo City-Erie County Health Department.

CHARLES S. CAMERON, M.D., recently a corps member of the U. S. Naval Medical Corps, has been appointed Medical Director of the American Cancer Society, New York, N. Y. Dr. Cameron is a Fellow of the American College of Surgeons.

J. ELLIOTT HALE,† formerly Director of the Industrial Hygiene Division of the Bureau of Health, Maine State Department of Health and Welfare, has taken up new duties as Superintendent of the Kennebec, Me., Water District.

GEORGE E. LAUBACH, licensed Health Officer in New Jersey, became Health Officer of the City of Elizabeth on January 15. He had previously been Health Officer of Dover.

EARL LUDLAM, D.D.S., has succeeded J. M. WISAN, D.D.S.,* as Chief of the Division of Dental Hygiene of the New Jersey State Health Department. He has been Assistant Director of the division for the past 10 years. Dr. Wisan resigned to become Director of the Division of Health Education of the American Dental Association whose headquarters are in Chicago, Ill.

CLINTON P. McCORD, M.D., of Albany, N. Y., has been appointed as Consultant in Psychosomatic Medicine in the New York State Department of Health, preparatory to the launching of a state-wide educational program related to emotional factors in disease. Dr. McCord has been practis-

ing neuro-psychiatry and analytic psychiatry for the past 35 years and is a Diplomate of the American Board of Neurology and Psychiatry and Consultant to the Albany Society for Advancement of Psychosomatic Medicine.

WILLYS M. MONROE, M.D.,† will become Health Officer of Greenwich, Conn., on July 1. He has been Health Commissioner of Pittsfield, Mass., since 1923 and served in both world wars, returning from recent military service with the rank of lieutenant colonel.

PHILIP S. PLATT,* Director of Lighthouse of the New York Association for the Blind spoke on voluntary health agencies at the annual meeting on April 15 of the Hartford, Conn., Tuberculosis and Public Health Society.

WILLIAM REINER-DEUTSCH, M.D.,† Director of Industrial Testing Laboratories and Technical Director of the National Brewers' Academy and Consulting Bureau, New York, N. Y. has been elected corresponding member of the Société de Biologie de France.

ELIZABETH P. RICE, formerly clinical professor of the social aspects of medicine at the Yale School of Medicine, New Haven, Conn., and assistant professor of the social aspects of nursing at the Yale School of Nursing, has been appointed the first Social Service Worker to the Faculty of the Harvard School of Public Health, Boston, Mass., as part of a new program to study the role of family life in the health of children. Miss Rice will commence a study of the preventive aspects of social work.

HELEN E. WEAVER, R.N.,† has been appointed as Consultant in Nursing Activities, the National Society for the Prevention of Blindness, New York, N. Y. Miss Weaver was formerly Consultant Public Health Nurse of the Division of Venereal Disease Con-

* Fellow A.P.H.A.

† Member A.P.H.A.

trol, New York State Department of Health, Albany.

SIDNEY I. WOLFSON,[†] has resigned as assistant to the District State Health Office, Freehold, N. J., to become Health Officer of Dover.

MARGARET POND ZEALAND was appointed nutritionist of the New Jersey State Health Department in February. Mrs. Zealand formerly served as dietitian in several hospitals in New York City.

Southern States

HAROLD V. DARNELL, B.Sc., has been appointed as assistant to ROBERT P. FISCHER, M.D.,* Secretary of the American Pharmaceutical Association, Washington, D. C. Mr. Darnell has been Executive Secretary of the Indiana Pharmaceutical Association since 1939.

ESTHER M. FINLEY,* Senior Assistant Nurse Officer of the U. S. Public Health Service, Washington, D. C., has been appointed Director of the Public Health Nursing Program for the Kanawha-Charleston Health Department, W. Va.

JOSEF JORDAN WEISSKOPF, M.D.,[†] recently appointed Surgeon in the Reserve of the U. S. Public Health Service, was called to active duty as of April 30. Since January, 1945, he has been Chief, Planning Branch, Medical and Sanitation Supplies Division, UNRRA.

Western States

NEW MEMBERS OF THE FACULTY AT THE SCHOOL OF PUBLIC HEALTH, UNIVERSITY OF CALIFORNIA, SAN FRANCISCO, ARE:

JACOB YERUSHALMY, Ph.D.,* as Professor of Biostatistics. Dr. Yerushalmy was formerly Principal Statistician, Division of Tuberculosis, U. S. Public Health Service. He recently

returned from Denmark where he served as Consultant in the tuberculosis control program.

EDWIN H. LENNETTE, M.D., Ph.D., who recently became the director of the Virus Laboratory, California Department of Public Health, has also been appointed Lecturer in Public Health. Dr. Lennette was a member of the Field Staff of the International Health Division of the Rockefeller Foundation until 1946 when he became Chief of the Medical Veterinary Division of the War Department.

DAVID FROST, M.D.,[†] became the first full-time Health officer of the City of Alameda, Calif., in February, 1948. He was formerly Chief of Venereal Disease Control in the Oakland Health Department.

Other Areas

ROBERT H. MARKS, M.D.,[†] Chief of the Tuberculosis Bureau of the Hawaii Territorial Department of Health, has announced his resignation, effective February 26. He returns to the mainland as Medical Director of Jefferson Sanatorium, Birmingham, Ala.

LUIS M. MORALES, M.D., former President of the Medical Association of Puerto Rico, was elected a member of the Council of the National Committee on Mental Hygiene at the organization's recent annual meeting in New York.

Deaths

EDWARD THOMAS DEVINE, Ph.D., known in social work and reforms, died in Chicago on February 27, at the age of 80.

HAROLD GILBERT MCGEE,* Charter Fellow of the Engineering Section of the Association, and Director of the Municipal Research Bureau of the Akron Chamber of Commerce since 1923, died at his home in Hudson, Ohio, on February 13. Besides being a tax and

* Fellow A.P.H.A.

[†] Member A.P.H.A.

finance expert in his early career he had also been Sanitary Engineer in the Michigan State and Jackson City Board of Health, and in the Ohio State and Lucas County boards. He was the author of numerous articles in engineering and public health journals as well as reports on municipal, school, county, and state budgets.

CONFERENCES AND DATES

- American Association for the Advancement of Science. Centennial Meeting. Washington, D. C. September 13-17.
- American Congress of Physical Medicine. Hotel Statler. Washington, D. C. September 7-11.
- American Dairy Science Association. University of Georgia, Athens, Ga. June 14-16.
- American Dental Association. Chicago, Ill. Week of September 12.
- American Dietetic Association. Boston, Mass. October 18-22.
- American Hearing Society. National Conference and Annual Meeting. Pittsburgh, Pa. May 19-23.
- American Home Economics Association. 39th Annual Meeting. Minneapolis, Minn. June 21-24.
- American Hospital Association. 50th Anniversary Convention. Atlantic City, N. J. September 20-24.
- American Library Association. Atlantic City, N. J. June 13-19.
- American Occupational Therapy Association. Hotel Pennsylvania, New York, N. Y. Sept. 7-11.
- American Public Health Association—76th Annual Meeting. Boston, Mass. November 8-12.
- American Public Works Association. Boston, Mass. October 17-20.
- American Red Cross. San Francisco, Calif. June 20-24.
- American Society for the Study of Sterility. Fourth Annual National Session. Chicago, Ill. June 21-22.
- American Society of Planning Officials. New York, N. Y. October 11-13.
- Biennial Nursing Convention — American Nurses Association, National Organization for Public Health Nursing, National League of Nursing Education. Chicago, Ill. May 31-June 4.
- Canadian Public Health Association. Vancouver, B. C. May 18-20.

- Colorado Public Health Association. Savoy Hotel, Denver, Colo. May 21-22.
- Conference of State and Provincial Health Authorities. Chicago, Ill. June 25-26.
- Connecticut Public Health Association. New Haven, Conn. May 12.
- First International Poliomyelitis Conference. Waldorf Astoria. New York, N. Y. June 12-17.
- Florida Public Health Association. Panama City, Fla. October 7-9.
- Fourth International Congresses on Tropical Medicine and Malaria. Washington, D. C. May 10-18.
- Georgia Public Health Association. Savannah, Ga. May 10-12.
- Indiana Public Health Association. Indianapolis, Ind. June 2-3.
- International Congress on Mental Health. London, England. August 11-21.
- International Federation of Housing and Town Planning. Zurich, Switzerland. July 20-26.
- Iowa Public Health Association. Annual Meeting. Burlington, Iowa. May 27-28.
- Massachusetts Public Health Association. Amherst, Mass. June 16-18.
- Missouri Public Health Association. Hotel Chase, St. Louis, Mo. May 12-14.
- National Association of Sanitarians. Portland, Ore. June 7-9.
- National Education Association of the United States. Cleveland, Ohio. July 5-9.
- National Gastroenterological Association. New York, N. Y. June 7-10.
- National Tuberculosis Association. Annual Meeting. New York, N. Y. Week of June 14.
- New England Health Institute. Amherst, Mass. June 16-18.
- New Mexico Public Health Association, Las Cruces, N. M. May 20-22.
- New York State Association of Milk Sanitarians. Buffalo, N. Y. September 22-24.
- Society of American Bacteriologists. Minneapolis, Minn. May 10-14.
- Tennessee Public Health Association. Andrew Jackson Hotel, Nashville, Tenn. May 3-5.
- Utah Public Health Association, with Western Branch A.P.H.A. Salt Lake City, Utah. May 25-27.
- Western Branch, American Public Health Association. Salt Lake City, Utah. May 25-27.
- West Virginia Public Health Association. Prichard Hotel, Huntington, W. V. May 27-28.

**ECONOMICAL
SANITIZATION
OF MILK UTENSILS**

with the

B-K
REG. U. S. PAT. OFF.
PLAN

You won't find a sanitation program today that is much simpler than the B-K Plan... at such low cost. You will get results with it, if you follow the easy directions. But remember—no system can produce these results without a certain amount of cleaning and good old fashioned elbow grease.

The B-K Plan stresses, after use, first the rinsing of utensils and equipment in cold water and then the scrubbing in hot water containing soapless General Manual Kleanser. Before milking, rinse milking machines, and utensils, and wipe cow's udder and teats with efficient, inexpensive B-K solution. These simple steps have helped many average-size farms get surprisingly low counts.

B-K* Chlorine-Bearing Powder contains 50% available chlorine. It speedily sanitizes dairy utensils and reduces the number of bacteria that result in poor quality... thermodurics and others. General Manual Kleanser loosens milk solids and really cleans.

Farm operating costs remain high... and past experience shows that milk prices are sometimes reduced without a proportionate lowering of costs. Recommend the simple, economical B-K Plan and you will help both farmer and city milk supply.

Literature explaining the role of bacteria in milk and their control is available for farmers. Programs of education also on request. Send for them—by writing to B-K Division, Pennsylvania Salt Manufacturing Company, 1000 Widener Building, Philadelphia 7, Pa.

The Role of **IODINE** *in Clinical Diagnosis*

- Diagnosis is the art or scientific process by which a disease is recognized. Success or failure in establishing a correct diagnosis depends in large measure on the use of reliable, safe and efficient clinical and laboratory procedures.

- Iodine compounds occupy a unique position as indispensable aids in providing X-ray evidence that is informative and most frequently complete. They supply the ideal contrast media for many diagnostic procedures—including bronchography, cholecystography, pyelography and myelography. Without these compounds, an accurate diagnosis might be difficult or impossible to make.

- Likewise in the fields of prevention and therapy, few medicaments serve such useful and varied purposes as Iodine with its many compounds and derivatives.

Air Pollution*

Engineering Section

SINCE the field that might be considered by this committee is large, it was believed advisable to restrict the scope of this year's report to one phase of the air pollution problem; namely, atmospheric pollution. The report does not include air pollution in enclosed spaces except as they may affect the outside atmosphere. It also seemed advisable in this initial report to limit its scope to certain available information on the source, character, and effect of atmospheric pollution and to some information on the methods of control.

Broadly speaking, atmospheric pollutants include smoke, dust, gases, vapors, fumes, and mists that may be present in the air and that create a nuisance, adversely affect animal or plant life, or cause property loss or damage.

Smoke and dust are no doubt the most widely recognized atmospheric contaminants. Investigation of atmospheric pollution in many cities, including the fourteen large cities in the United States surveyed¹ by the U. S. Public Health Service (1931-1933), have recorded the conditions that exist in some urban communities in the United

States and have brought out certain fundamental relations that are of importance in organizing and carrying out smoke and dust abatement programs.

Ely² has pointed out that "the so-called smoke abatement problem divides itself into two parts, the smoke problem and the dust problem. The smoke problem, i.e., smoke stacks, is one of combustion and it is always possible with proper equipment and design to stop a smoking stack. The other problem, that of dust and dirt, is a matter of air pollution, and its solution depends on many factors." It should be realized that the smoke stack, even when not smoking, may be the source of fly ash and dust, particularly in the case of pulverized coal furnaces with ineffective fly ash catchers.

In reference to dustfall due to substances other than smoke, the Chicago Association of Commerce in a report on air pollution points out the importance of "refuse in alleys, dust in the streets and vacant lots, dirt on rooftops, and material from tires, clothing, shoes, buildings and all other things that 'wear' as a result of busy city life. At times even soil from farms hundreds of miles away is important." Another form of dust particle that should not be overlooked is the pollen which, in certain concen-

* Report of the Committee
COMMITTEE ON AIR POLLUTION
Organized 1946.

trations, is responsible for allergic reactions in susceptible individuals.

To these more common forms of smoke and dusts, present to some extent in the air of practically every community, must be added the gases, fumes, vapors, and mists, originating particularly from industrial establishments, that are present in some communities as atmospheric contaminants in sufficient concentration to produce a nuisance, cause property loss, and in some cases affect the public health.

While the presence in the atmosphere of any of the contaminants mentioned may conceivably have health implications, it has always been difficult, and in many instances impossible to demonstrate actual damage to health.

Stead³ has included in the industrial contaminants that cause nuisances: (a) inert smokes and dusts, (b) mucous membrane irritants, and (c) malodorous substances.

Smokes that result from the combustion of fuel contain soot, fly ash, and unburned or partially burned fuel. Smoke alone, for example, in excessive quantities is disagreeable, discomforting, and of economic significance, but the evidence so far collected has not been able to establish a definite relationship between smoke and health.

The discharge into the atmosphere of dusts from industries such as smelters, cement plants, rock crushers, sand blast plants, and roofing plants, and of some of the organic dusts may, however, have health implications.

Mucous membrane irritants emitted from industrial plants include respiratory irritants such as sulfur dioxide, chlorine, and phosgene, and eye irritants such as acrolein, butadiene, chlorine, and hydrogen sulfide. The discharge of irritating gases into the atmosphere in objectionable quantities will naturally cause serious complaints.

Malodorous substances may originate from a variety of industries and other

sources including rendering plants, tanneries, soap factories, glue plants, oil refineries, sewage disposal plants, internal combustion engines, etc. Stern⁴ points out that "the chemical groups most frequently responsible for unpleasant odors are the sulfides, disulfides, mercaptans, thiocyanates, isocyanides, compounds analogous to the foregoing of selenium or tellurium, and aldehydes" and that "many of these substances are recognizable as malodorous at less than 0.1 p.p.m., some at as low as 0.0000001 p.p.m."

Various methods and techniques have been devised for locating and studying the source, distribution, and effect of atmospheric pollution. Unless the source and distribution of the contaminant can be determined by direct observation, the discovery of the origin of atmospheric contaminants may be a difficult one requiring the exercise of highly specialized technical skills. The "Report Submitted to the Trail Smelter Arbitral Tribunal," *Bulletin 453*, U. S. Bureau of Mines,⁵ is an illustration of the exhaustive technical investigation that may be necessary to determine the damage resulting from the discharge of SO_2 from a smelter under the meteorological conditions that existed in the area surrounding this plant.

A number of devices such as electrostatic and thermal precipitators, impinging apparatus, filters, and atomizers, have been developed for the sampling of dust and bacteria in air. These devices are described in various publications. Probably the most common measure of smoke density is the Ringelmann⁶ chart, which is used as a guide in the enforcement of many smoke ordinances.

To establish proof as to the distribution from a given source of such common substances as smoke or fly ash, a number of methods have been used or suggested. One method consists of adding radioactive salts to the smoke

stream in a stack and recovering the radioactive components in the area under observation. Another method described by Sinatt⁷ is the identification of cenospheres, which are hollow spheres that are produced when certain solid fuels are burned at temperatures above 600° F. in a limited air supply. If deposits of these cenospheres are recovered from the area of complaint, they constitute evidence of the source of the trouble.

An indirect effect of smoke and dust is the diminution of sunlight and the increase in fogs, clouds, and haze. Fogs accentuated by smoke and dust add to certain hazards associated with motor and airplane transportation. This hazard has been considered in connection with the location of some important airports in this country. Studies have been reported by Drinker⁸ on methods for eliminating fogs at airplane landings, but these have apparently not yet reached a practical stage.

The health hazards associated with the release of radioactive substances into the atmosphere have aroused world-wide interest. In times of peace some of the actual and potential sources of these radioactive atmospheric contaminants are plants producing plutonium, uranium, and radioisotopes, and possibly to some extent laboratories conducting experiments with radioactive substances. Studies⁹ have been made on the possibilities of the release of radioactive dusts and gases from atomic energy plants, and progress has been made in developing methods for health protection against atmospheric contamination from such plants. Much information on this subject is not yet released for publication.

The control of pollens responsible for allergic reactions in certain individuals has been given more attention in the past few years. Various methods have been tried to control hay fever pollen-producing plants, including cutting the

plants before they blossom, and chemical treatment. Among the chemicals recently used for the destruction of these plants, especially ragweed, which is a most important member of the hay fever producing group, is dichlorophenoxyacetic acid commonly known as 2,4-D. This is a synthetic plant hormone which disturbs plant growth and eventually destroys the plant. The chemical is usually applied in the form of a spray but may be dusted. A large number of communities are reported to have used 2,4-D, among them the City of New York.

Sol Pincus has made the following brief statement for this report concerning the use of 2,4-D by the New York City Health Department:

In 1946, it was estimated that 10,000 acres were infested with ragweed in the five boroughs. It was decided that the use of the new chemical, 2,4-D, dichlorophenoxyacetic acid, would be the most economical method to control ragweed in New York City. Starting very late in the season, we were able to control the growth of 3,000 acres of ragweed, which contributed probably to the unusually low atmospheric pollen concentration during the ragweed season. It was a coöperative program. Equipment and personnel were contributed by the coöperating departments with the Health Department coördinating the work, furnishing the technical direction, chemicals and supplies.

At the close of the 1946 season, a survey was conducted by the Police Department which resulted in 85 Precinct maps showing the locations and areas of ragweed growth in the city. These maps served as guides in the preparation of plans for the 1947 campaign.

It was estimated that 8,000 acres had to be treated in 1947. We obtained six high-pressure power spraying units from the War Assets Administration, two skid-mounted decontaminating units from the U. S. Public Health Service, and various supplementary equipment from the War Assets Administration.

Public and private vacant properties were treated alike without making a charge to the private owners. During the 1947 season, it is estimated that approximately 4,000 or 4,500

acres will be sprayed. It has been adjudged that one application of the chemical is sufficient to kill the ragweed or prevent the pollination and seed production.

A spray solution containing 1,000 p.p.m. of 2,4-D was used. This was applied at the rate of approximately 300 gal. per acre. The sodium and ammonium salts of 2,4-D were used. The cost of the chemical was approximately \$1.25 per lb., and the cost for the area sprayed including labor and use of equipment and chemicals, was approximately \$11.00 per acre, in 1946. Figures for 1947 are not yet available.

It was noted that the area sprayed during July and August of 1946 showed very little or no growth of ragweed during the 1947 season.

Many neighboring communities have instituted similar programs in reduction of ragweed pollen. This department coöperated in making available our experiences and also in giving a training course under New York University direction to health officers and other officials of these communities.

While encouraging results have been obtained in the elimination of hay fever pollen-producing plants in certain areas where regulatory measures are in effect, the control of pollens from outside areas still remains a problem. Investigations have shown the long distance that pollens may travel under meteorological conditions favorable to their migration. The question, however, of the kind and the concentration of hay fever-producing pollens, regardless of their source, becomes an important factor in dealing with any situation.

Various methods have been developed for sampling and counting air-borne pollen and for computing the results of such examinations in terms of pollen concentrations in the atmosphere. Dahl and Ellis,¹⁰ after a study of the methods for computing pollen concentrations state that "those which utilize volumetric factors derived from Stokes' law are less accurate than those methods which employ a unit area basis," and that "it is to be desired that reports should include a record of the amount of pollen per unit of area of the exposed

slide, whether volumetric data are computed or not."

The measurement of gases and vapors emitted from various sources presents serious difficulty when low concentrations are encountered, because the lower limit of most chemical methods is around 1 p.p.m. by volume. Some instruments, however, have been developed that are helpful in this connection. The Thomas Autometer¹¹ is one apparatus which will collect its own samples and measure and record concentrations of sulfur dioxide and sulfur trioxide as low as 2 parts per billion. This machine has also been developed to measure separately the concentration of other gases, including hydrogen sulfide, carbon disulfide, ethyl mercaptan, and thiophene. The method, at a higher operating temperature, is also applicable to chloroform, carbon tetrachloride, ethylene chloride and chlorobenzene.

Whipple¹² in 1921 pointed out many of the fundamentals in regard to odors and their relationship to odor nuisances in a discussion on odors and their travel habits.

The measurement of odors from various sources is attended by many difficulties. Various methods^{4, 13-15} that employ the sense of smell of the observer have been devised for evaluating the intensity of odors. Odor scales^{4, 16} indicating threshold odor concentrations and tables showing the concentrations and characteristics of various readily perceptible substances in air have been prepared.

Hemeon and Hatch¹⁷ point out that "osmometry is in need of research cultivation; we know little about it. Moreover, the subject of odors is inextricably entangled with psychological factors which although usually foreign to chemist and engineer cannot be ignored. The facts of olfactory fatigue and revivification by periodic variation in concentration are relevant, as is the

law expressing the logarithmic relation between sensory response and the magnitude of stimulus—i.e., concentration of the vapor or gas.”

The instrumental measurement of odors presents a difficult problem, however, because odors are due to the perception of molecules rather than a response to conditions. Some attempts have been made to develop physical methods of measurement, such as the work of Dyson,¹⁸ who used the Raman shift for this purpose. Apparently, however, no practical method has so far been devised, and there is need for research in this field.

A large amount of technical work has been undertaken on methods to prevent atmospheric pollution from smoke, dust, gases, vapors, and fumes.

Probably the greatest amount of attention has been focused on smoke control, since this kind of air pollution is obvious and attracts public attention. Fuels and combustion equipment and methods have been studied. As a result detailed information is available on the construction and operation of nearly all types of fuel burners to improve or correct combustion difficulties.

Extensive studies have been made on the polluting substances released from stacks and the dilution that may be anticipated under varying meteorological and other environmental conditions. Investigations of the U. S. Bureau of Mines¹⁹ indicate that factors of dilution of the polluting material at given points of travel can be computed with rough accuracy for a given horizontal distance if the stack velocity and wind velocity are known.

The importance of meteorological and other environmental studies should not be overlooked in selecting new plant sites, especially where gaseous waste disposal problems are anticipated.

Meteorological factors are involved both in the creation and in the solution of atmospheric pollution problems. For

example, there are the disturbing effects of temperature inversion, which cause a natural rise of atmosphere containing contaminants when the earth's surface is warmer than the air, but produce the formation of a so-called “lid,” holding pollution down near the earth's surface, when the earth is colder than the air.

The control of industrial dusts, gases, vapors, and fumes at the source also presents difficult technical problems. However, considerable progress has been made in their solution. Hemeon and Hatch¹⁷ mention among the available control methods the following: “scrubbing and absorption towers for vapors and gases, especially acid gases, various types of dust and fume collectors, and miscellaneous chemical processes such as combustion of organic contaminants or neutralization in conjunction with scrubbing.” In some cases the use of raw materials free from objectionable impurities may eliminate the difficulties, while in others the utilization of the contaminant in the manufacture of a useful by-product may provide a solution. These authors mention the substantial body of experience in gas cleaning in industry, much of which has not been applied to atmospheric pollution control. They emphasize the need for “further research and field study, particularly with respect to the collection of dust and fumes, to provide basic information on stack gas cleaning equipment and other control measures especially for small plants.”

Many large and small cities in the United States have recognized the problem of atmospheric pollution and have passed ordinances regulating smoke or smoke and dust, while some of the large cities have a relatively complete coverage of the important atmospheric contaminants. No attempt has been made in this report to make a nation-wide survey of the administrative control of atmospheric pollution. However, for illustrative purposes, information was obtained

on control practices in three large cities; namely, New York, St. Louis, and Los Angeles, which have organized control programs.

Control of atmospheric pollution in New York City* is an activity of the Bureau of Sanitary Engineering of the Department of Health under the general supervision of the Sanitary Engineer Director of the Bureau.

A special force of smoke inspectors has been organized consisting of one supervising inspector and six field inspectors. The regular district inspectors (approximately 70) take care of the routine complaints of smoke, odors, fumes, etc. The special smoke inspectors make investigations involving larger plants, utilities, harbor craft, etc. They also make surveys of air pollution in areas of greatest intensity of smoke discharge. The supervising smoke inspector checks over the work of the regular district inspectors in air pollution.

The district inspectors, in groups of five are given an intensive course by the supervising smoke inspector in methods of investigating and controlling air pollution. The course takes about six weeks.

Eleven committees have been organized to coöperate with the Health Department. These committees represent: (1) real estate and industry, (2) railroads, (3) utilities, (4) harbor craft, (5) solid fuels, (6) fuel oils, (7) public health aspects, (8) laws and legislation, (9) plant operation, (10) city departments, (11) public coöperation. The committees have met in most instances monthly with the Commissioner of Health and the Director of the Bureau of Sanitary Engineering.

Monthly sootfall collections have been made for the past five years from 13 locations, mostly in areas of high smoke

discharge. These monthly samples have been analyzed for solids and ash in both the water-soluble and water-insoluble components of the sample. The results obtained, when compared with those of previous periods, give a rough estimate of the increase or decrease in smoke discharge over wide areas of the city.

In comparison with the sootfall records obtained during a WPA air pollution survey in 1936, recent results show that there was a large increase in sootfall during 1943 and 1944, which has subsequently lessened considerably. The increase during the war period was concurrent with a tremendous overloading of coal-burning power plants.

A great amount of rehabilitation of fuel-burning plants and installation of soot collectors has been accomplished during the past two years. The large electric companies have made significant improvements at their generating plants at a cost of millions of dollars. A number of the industrial plants, hospitals, and mercantile establishments also have improved their fuel-burning equipment and put in soot collectors.

A detailed program for the extensive training of janitors and superintendents has been prepared and will start in the fall of 1947 in some of the Board of Education high school buildings.

At the same time that the janitors and superintendents are acquainted with methods of firing furnaces and preventing smoke and odor complaints, they will be given instruction in rodent and vermin control and in the sanitary maintenance of buildings.

A program for future extension of this work has been drawn up and will include the addition to the department of a mechanical engineer—an expert in smoke control work, two assistant engineers, and a number of field inspectors. This expansion is now awaiting the allotment of funds by the city authorities.

* Information concerning New York City was furnished by Sol Pincus, Senior Sanitary Engineer, New York City Health Department.

St. Louis* has attracted considerable national attention because of the extent of its air pollution problem and the efforts made to control it. These efforts, principally due to the anti-smoke ordinance and its enforcement, appear to have produced a definite and permanent improvement. This is particularly true of sootfall, visible smoke, and volatile sulfur compounds in the air caused by combustion of solid fuels.

The city, being located close to the Southern Illinois high-volatile bituminous coal fields, uses such fuel in great quantity. The anti-smoke ordinance secures the control of the pollution of air from such fuel use by a multiple approach:

1. It prohibits the use of high-volatile bituminous fuel except in mechanically-fired furnaces and power plants.
2. It requires the air- or water-washing of all high-volatile bituminous fuels to reduce sulfur compounds.
3. It sets certain limits for fly ash emission which invariably require collector installations on powdered-fuel power plants.
4. It has the usual and necessary measures of promoting proper firing, registration of new heating installations, maximum density and duration limitations for smoke emission and a qualified inspection force.

Enforcement of the anti-smoke ordinance is the responsibility of the Commissioner of Smoke Regulation who directs a division which is a part of a Department of Public Safety. The Health Division, a part of the Department of Public Welfare, works closely with the smoke control office and has assisted in providing some technical assistance, particularly along the lines of laboratory and air analysis techniques.

Most of the present air pollution problems center in fly ash emission from plants permitted to postpone collector installations due to wartime equipment

shortages and such emission from large plants near to but outside the city limits and, therefore, beyond the city's legal jurisdiction. Some smoke and chemical odor problems occur at times due to such materials being carried over the city from the highly industrial area just to the east of the city, in Illinois.

The remaining air pollution problems are, in general, not city-wide but rather limited to local neighborhoods, and are due to isolated industries producing objectionable dusts, fumes, or gases. Almost invariably, these cannot be demonstrated to be either a health hazard or a public nuisance (involving property damage over a considerable area). At present, the city charter and ordinances give power to the Health Commissioner to declare and abate public nuisances (after hearings). Those air pollution situations which come within this category can be and have been controlled by this legal means. The Health Division has extensive air sampling equipment and experienced personnel in its Industrial Hygiene Section. Through these means, it is able to locate responsibility and recommend and enforce corrective action.

The inadequacy of present laws for air pollution problems not of public nuisance proportions is recognized. Plans are now being made for the formulation of an overall air pollution control ordinance. Provision for an adequate and qualified staff is also planned.

The Los Angeles* air pollution control problem differs from that of most eastern cities. No coal is burned; instead gas is used by all homes and by most apartment buildings and hotels. In summer most industrial power plants are operated by gas, while in winter large power and heating installations employ oil burners.

The greatest accumulation of smoke

* Information concerning St. Louis was furnished by John Buxell, Engineering Director, St. Louis Health Division.

* Information concerning Los Angeles was furnished by Charles L. Senn, Engineer-Director, Sanitation Bureau, City Health Department.

and other air pollution is associated with hot summer weather when visible smoke production is at a minimum. This is due to the occurrence of extreme temperature inversions coupled with an almost complete absence of wind and turbulence.

A city ordinance places certain responsibilities for air pollution control on the Los Angeles Health Department. The Air Pollution Control Division of the City Health Department is one of the divisions of the Sanitation Bureau. The division personnel consists of a director, four inspectors and a clerk-stenographer. One inspector is responsible for collecting samples and for studies of industrial fumes and gas nuisances. A second devotes his entire time to railroad smoke control. A third is concerned principally with the control of smoke from Diesel trucks. The fourth inspector is assigned to the harbor district which includes the two major oil refineries which are located in the city.

Most of the control work is based on the use of the Ringlemann chart and on organoleptic tests. The facilities of an industrial hygiene laboratory are available. Samples are collected with electrostatic precipitators and two scrubbing devices. The main laboratory effort has been directed toward attempting to isolate the particular chemical that acts as a lacrimator, since eye and throat irritations are the principal causes for complaint by citizens.

The present status of the organization of the Department of Health is somewhat questionable because of newly enacted state legislation. An amendment to the State Health and Safety Code sets up a state-wide control system concerning smoke, dust, obnoxious gases, and industrial waste fumes discharged into the air. The act provides for the creation of smoke abatement districts that would be under the direct supervision of county boards of super-

visors, whose authority would supersede that of an incorporated city except where local ordinances are stricter than the state law.

It is obvious that the engineer must play an important part in the control of air pollution. The position of the engineer in this field and the knowledge necessary to function satisfactorily were discussed by Phelps and others²⁰ in a symposium on "The Role of the Engineer in Air Sanitation," of the American Society of Civil Engineers, 1941.

DISCUSSION

The control of atmospheric pollution is an administrative and technical problem that can be solved by engineering means. While there is no epidemiological information that will permit evaluation of the public health significance of many of the recognized air contaminants after they have been discharged into the atmosphere, their importance from the standpoint of the comfort and general welfare of the public and the individual involved cannot be overlooked.

The pollution of the atmosphere by dust, smoke, fumes, gases, vapors and mists as well as by pollen, should engage the attention of health departments at all levels of government, and qualified engineers should be called upon to meet health department responsibilities in this field of environmental sanitation.

The organization of the necessary administrative and technical activities in a health department will be governed to some extent by the facilities that can be made available. Trained professional personnel and technical facilities are required if air pollution is to be abated.

Since other departments of government too are concerned, directly or indirectly, with this problem, a coordinated program of activities is indicated.

There is an obvious need for research on many technical phases of atmospheric

control, especially on the meteorological factors affecting atmospheric pollution, methods for the instrumental measurement of odors, methods for the collection of dusts and fumes from industries, and methods for the control of air-borne pollen.

Course on Financial Problems in the Nursing Field

A short course on Financial Problems in Schools of Nursing, Hospital Nursing Services and Public Health Nursing Agencies, 2 semester hours, will be given July 12 through 23, 1948, in the Division of Nursing Education, Indiana University, Bloomington, Ind.

This course is especially designed for directors of basic nursing curricula, directors of hospital nursing services, and directors of public health nursing

agencies. It should also be of interest to board members of public health nursing agencies, hospital administrators, and college and university administrative officers who are concerned with basic nursing curricula.

Information and application forms may be secured by writing Mrs. Eugenia K. Spalding, Director, Division of Nursing Education, Indiana University, Bloomington, Ind.

The Sanitary Engineer in Hospital Construction and Maintenance*

A. H. WIETERS, F.A.P.H.A.

Director, Division of Public Health Engineering and Industrial Hygiene, State Department of Health, Des Moines, Iowa

THE greatest hospital construction program in the history of this country was launched with the passage (by the 79th Congress) of the Hospital Survey and Construction Act (P.L. 725). This act authorizes an annual appropriation of \$75,000,000 for each of five years for grants-in-aid for the construction of hospital facilities. The program is to be administered largely by the states under the general supervision of the U. S. Public Health Service. One of the provisions in the act requires the states participating in the program to regulate the operation and maintenance of the hospitals built with federal aid.

Only a few states previously regulated construction and operation of hospitals, but now, for the first time, the construction, maintenance, and operation of most hospitals will be under state regulation. In about three-fourths of the states, the health department will be the administering agency.

A comprehensive nation-wide inventory of existing hospitals and survey of needs for hospitals in the United States in 1945 revealed not only a great shortage of adequate hospital facilities, but also a serious maldistribution of existing facilities. Thus, a large segment of the total population finds itself with no hospital facilities readily available. Furthermore, the inventory revealed that many of the existing services failed to

provide acceptable hospital care by any reasonable modern standard because of grossly inadequate physical plants and staffs. Consequently another large segment of our population lacks satisfactory hospital facilities.

Time will not permit, nor is it within the scope of this paper, to discuss these needs. Suffice it to say that the objective of the present program is to assist the several states to survey their needs for hospitals, to develop plans for construction of facilities for furnishing adequate hospital services for all the people, and to construct such hospitals.

Many professional skills must be combined in the development of construction plans for a modern hospital. The hospital is more than a building. It is a workshop and, as such, the building layout and the type and arrangement of equipment must be carefully planned so that the entire facility will function effectively and economically. The hospital and its equipment are the tools used by the physicians, the nurses, and allied technical hospital personnel in caring for the sick.

Obviously, those responsible for operating the hospital must have a voice in the functional planning. Equally important are the engineers and architects who translate the functional plan into a working drawing and a finished facility. The final plan must be the result of close teamwork of those representing the various and highly technical skills involved.

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

In the operation and maintenance of a hospital, again teamwork is essential for successful and economical service. All of the engineering problems encountered in ordinary building operation, plus many additional ones, must be solved. These are made the more difficult in that even short lapses in operation of any of the equipment or appurtenances cannot be tolerated and much maintenance must be carried out while the plant is in full operation.

The sanitary engineer should be a member of such a team. While sanitary engineering principles have long been applied in hospital construction and maintenance, the sanitary engineer has not been closely identified with hospitals to any great extent in the past. A few large architectural firms specializing in hospital design have formerly employed sanitary engineers; however, most architects do not have sanitary engineers on their staffs. In only a few of the states have architectural plans been subject to review by sanitary engineers. Likewise, in but few of the states and larger cities has the sanitary engineer been called upon to contribute his services in the operation and maintenance of hospitals.

Most of the principles of hospital sanitation are the same as are applied to other types of buildings; however, the hospital is unique in that many of the occupants are potential, if not known, active carriers of disease. Therefore, faulty design, breakdown, or lapse in proper use and operation of equipment is fraught with greater danger of spread of disease than would be the case in other buildings. Also the occupants are, for the most part, in a weakened condition and thus are more susceptible to ill-effects from faulty environment than are occupants of other buildings.

As previously stated, in both the design and operation of a hospital, the functional as well as the architectural and engineering phases must be coördi-

nated for efficiency and economy. The sanitary engineer is in a unique position by training and experience to serve in a liaison capacity between those doctors, nurses, hospital administrators, and others responsible, on the one hand, for operating the hospital, and the engineers and architects responsible for design, construction, and equipping of the hospital on the other.

What is the extent of the sanitation problems in hospitals? Complete morbidity statistics would be the best criterion for the evaluation of sanitation problems. Unfortunately such data are very incomplete. It is known that there are numerous recurring outbreaks of diarrhea and skin infections among infants in hospitals, of food poisoning, and of cases of cross-infections which are never reported to health authorities. It is also known that many of these cases of disease result from faulty environment. That potential hazards, readily recognized by sanitary engineers, are commonly found in hospitals is indicated by many surveys that have been made. In existing buildings, serious defects in plumbing have been very common. According to a recently published report, food sanitation in the hospitals in one of our largest cities was rated lower than in the public restaurants in the same city, and in the latter was far from satisfactory. Crowding, lack of sufficient good equipment, and unsatisfactory working spaces and equipment are known in many cases to be more responsible for breaks in technique which result in spread of disease than incompetence of employees.

The sanitary engineer is largely concerned with the sanitary features of structures and equipment and their maintenance and operation. However, these are so closely related to functional and other features of design that a distinct line of demarcation cannot be drawn. The layman, and even other professional engineers, too often do not

seem to realize that the sanitary engineer is basically trained in fundamental engineering principles in common with other professional engineers in addition to his training in public health.

Many phases of professional engineering are involved in hospital design, construction, maintenance, and operation, and more than one specialty is frequently required in the design of a piece of equipment. For example, a dishwashing machine may be designed by a mechanical engineer. However, there are important sanitary implications in the design, the installation, and the operation of such a machine which must be considered in the interest of public health.

The services of the sanitary engineer in hospitals should be utilized in two ways: (1) in design, maintenance, and operation of facilities and equipment which comes more or less within the scope of his usual activities, many of which, however, have special significance in the hospital; (2) in cooperating with the medical and allied professions, in further study of potential health hazards in the environment of the patient about which little is known.

In the first category, the following items may be enumerated:

Site—Many future sanitary problems of maintenance and operation can be avoided by proper site selection. Availability of an adequate, safe water supply, proper drainage, and means of safe and economical disposal of sewage and wastes are very important factors in site selection. Insect breeding areas, sources of noise, smoke, and dust in the immediate area must be given careful consideration.

Sewage disposal—Where no sewer system is available, sewage disposal may be a particularly troublesome problem. Because of the potentially infectious nature of the sewage from a hospital, a high degree of treatment and special precautions are necessary. Large volumes of laundry and cleaning wastes may complicate the treatment problem. Operation and maintenance of these facilities likewise require special knowledge, usually not possessed by hospital operating personnel.

Plumbing—Because of a relatively large quan-

tity of infectious material which is introduced into the drain system, plumbing is of special importance. Many special fixtures used in hospitals, and which are not in common use elsewhere, are inherently dangerous unless adequately protected. These factors make precautions against backflow doubly important. Relatively large amounts of water are used in hospitals and peak demands are high. To assure adequate and uninterrupted pressures in all parts of the building under all operating conditions requires very careful design. For the same reason, drains must be carefully planned.

Food Handling—While general sanitary principles in the storage, preparation, and handling of food and the cleansing and disinfection of utensils apply, opportunity for contamination is so great and effects may be so disastrous that unusual precautions are necessary.

Garbage and Waste Disposal—The hospital has the usual problem of the proper disposal of ordinary kitchen garbage and rubbish. Also the handling and sanitary disposal of contaminated and infectious material, which is peculiar to hospitals, presents a problem.

Lighting—In addition to the hygienic and safety aspects of general lighting, special lighting in certain areas, such as surgery, dispensary, formula room, etc., is imperative. Uninterrupted lighting in certain areas is a must item.

Heating and Ventilation—In addition to general heating and ventilation, several areas within a hospital require special consideration.

Laundry—Although commercial laundering practices are quite well standardized, and in modern practice effective germicidal action is incidental to thorough cleansing, the handling of soiled laundry requires special attention.

Sterilization Equipment—Possibility of contamination of the water supply or of the contents of sterilizers is extremely important and the very nature of this equipment makes it difficult to construct sterilizing equipment which is fully protected. Also unless the equipment is meticulously operated and maintained, complete sterilization results will not be uniformly obtained.

General Sanitation—There are many other considerations which will facilitate general cleanliness and good housekeeping, such as floor and wall construction of durable, easily cleaned material, and adequate and conveniently located hand washing and toilet facilities for employees. Insects and rodents often constitute serious problems in hospitals, and control measures, both as to construction and operation, are of great importance.

In a second category, of first importance is the study of the spread of disease from patient to patient, from patient to employee, or the reverse, within the hospital. While this is primarily the function of a trained epidemiologist, the services of a sanitary engineer should be used to a greater extent. In the past, to the writer's best knowledge, sanitary engineers have had little opportunity to assist in such investigations, although it has been common practice for many years to utilize the services of the sanitary engineer in other epidemiological studies where environmental factors were involved.

There are other items on which further information is needed. While perhaps some of these studies should primarily be conducted by professional personnel other than sanitary engineers, it is believed that sanitary engineers could render valuable assistance. No attempt is made to enumerate all such items, but the following will illustrate some of the needs:

Is general ventilation (including temperatures, humidity, and air movement control) indicated in the hospital? Is it permissible to recirculate air in the surgery, the nursery, the labor and delivery rooms, and contagious wards? Is it ever permissible to recirculate air from any one patient area to another?

In view of the limited studies that have been reported, and of the lack of conclusive evidence of substantial benefit, what policy should be adopted on use of ultra-violet ray air sterilization in surgery, nursery, contagious wards, formula room, etc.? On use of aerosols?

Should completely separate dishwashing facilities be required for a contagious section or tuberculosis section? If so, is it permissible to return clean dishes from this section to the general kitchen for serving?

Should linens from the contagious section, tuberculosis section, etc., be laundered separately from the general

laundry? Should linens receive germicidal treatment before being removed from these sections to the hospital or a commercial laundry? If given no such treatment, what special precautions should be taken by personnel who handle such linen in the laundry?

Should feces and urine from known or suspected cases of intestinal infection or other infectious material be germicidally treated before discharge into a public sewer? Or into a private sewer?

What special precautions should be taken in handling and storage of patients' clothing?

Should mattresses in the contagious section be sterilized after discharge of each patient? Does laundering at low temperatures (wool 120° F.), particularly from the contagious section, provide ample protection?

Is it permissible to include food left on plates from the contagious or the tuberculosis section in garbage which is fed to hogs?

Adequate information is not available on peak water usages on which to base intelligent design of water piping and drain systems.

No public laboratory now exists where hospital plumbing fixtures and appurtenances can be tested.

These and many other questions remain to be answered.

One of the requirements for federal aid under the Hospital Survey and Construction Act is that states must regulate the operation and maintenance of hospitals receiving such aid. Under this stimulus, many of the states already have, and most of the others probably will make, provisions for licensing of all hospitals. Sanitation should play a prominent part in any such regulation and thus for the first time in many states the sanitary engineer will have an opportunity to participate in hospital planning, operation, and maintenance.

In most hospitals, various individuals

have responsibility for some phase of sanitation with little correlation or general direction. Probably very few hospitals are large enough to justify employment of a full-time sanitary engineer, yet sanitation problems are of sufficient importance in hospitals of all sizes to warrant more attention than has been accorded them in the past.

It would be desirable, wherever feasible, to have one person on the hospital staff, preferably with sanitation training, who is responsible for all phases of sanitation, with such assistance and guidance of local or state health department sanitation personnel as may be needed.

The state and local health department sanitary engineers should be available to review plans and specifica-

tions, from a sanitation standpoint, for new construction and for revamping existing structures; to make sanitary surveys of existing hospitals and advise as to physical changes and operation procedures which would improve sanitary conditions; to advise and guide personnel who are responsible for operation and maintenance of equipment; to participate in inservice training of employees; and to study means of improving hospital sanitation.

With the advent of a huge hospital construction program, coupled with the control of operation and maintenance of most hospitals by the state, the sanitary engineer is presented an opportunity to extend his services into a field with which he has not been closely identified in the past.

Sanitary Ventilation*

W. F. WELLS, F.A.P.H.A.

*Associate Professor of Research in Airborne Infection, University of Pennsylvania
School of Medicine, Philadelphia, Pa.*

FIFTEEN years ago we demonstrated before a joint meeting of these sections an apparatus for the study of the bacterial behavior of air¹; at the meeting ten years ago we described a method for the measurement of sanitary ventilation²; five years ago we discussed air disinfection in day schools³; this paper considers the sanitary significance of ventilation. Paradoxically, the hygienic interest in ventilation waned with rise of sanitation. Before the patterns of spread of ingested infection and inhaled contagion were clearly differentiated, the sanitary disproof of the miasmatic origin of enteric infection discouraged further belief in air-borne respiratory contagion; transfer of contagious disease then was ascribed to personal contact.

Even in the most congested districts of our largest cities, contact infection was of secondary consideration in the environmental control of typhoid fever. The gradual decline in residual typhoid resulting from elimination of carriers created by water-borne infection came as a minor and unpredicted bonus, compared to the reduced rates immediately following an investment in pure water.⁴ In the control of contagious epidemics on the other hand, such as measles, for instance, or influenza, where a single case can initiate a contagious chain of

growing generations of infection, quarantine has until recently been the only environmental means available. Whereas the relatively static dissemination of infection in space dominates spread of typhoid fever and other water-borne intestinal infections, the propagation of air-borne respiratory contagion in time is intrinsically dynamic.

DYNAMICS OF CONTAGION

The autocatalytic nature of contagion has been expressed mathematically for theoretical epidemics in homogeneous aggregations homogeneously exposed. "Almost all workers in the analytical theory of epidemics assume that the rate at which an infection passes in a population is proportional jointly to the product of the number of persons I who are infectious and the number of persons S who are susceptible to the infection. This is called the law of mass action. Thus, if the rate of new infections be C the law is written as $C = rIS$, where r is a constant,"⁵ r then being the effective contact rate. This elementary equation approximately describes the dynamic pattern of intra-aggregational spread of contagion.

EFFECTIVE CONTACT RATE

In the study of contact infection, measles has played a leading role and is suggested as a natural index for study of the dynamics of droplet nuclei contagion. The value of S in the above formula is directly indicated; persons

* Presented at a Joint Session of the Engineering and Industrial Hygiene Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

The work reported in this communication was supported by grants from the Commonwealth Fund.

are assumed to be susceptible before, and immune after, having measles. Also, the value of I is generally ascertainable; direct exposure to a previous case the second week before symptoms appear can usually be detected; younger children normally contract the disease when exposed in the home.

In a quantitative study of effective contact the suburban primary school offers decided advantages: children ordinarily enter school before having measles but contract this disease before graduation; in school they are homogeneously exposed within standard classrooms; both exposure and effective contact can be established through attendance records.

By such means the effective contact rate r of measles in classrooms of three suburban primary schools during the past four years has been evaluated.⁶ Among approximately 791 susceptible

classmates of pupils who became ill with measles while attending classes (a unit of exposure), 87 contracted the disease after a normal incubation period. An effective contact rate of 11.0 per cent is consistent with unproductive exposures observed in schools⁷ and should theoretically yield in the formula some indication of productive exposures in classrooms meeting with Pennsylvania code requirements of ventilation.

INTRAGROUP CONTAGION

As compared with 80 or 90 per cent secondary attack rate among primary school children in families reported by Chapin,⁸ an effective contact rate of 10 per cent in classes may seem unimpressive, but this represents merely the static infection in a single generation. Most of the infected pupils attend class until symptoms appear, and by re-exposing their class become the infectors

THRESHOLD SANITARY VENTILATION

CHART I—Diagram Relating Sanitary Ventilation to Air-borne Contagion

Area inside each link of chains of generations of infection in irradiated and unirradiated schools during 1941 epidemic corresponds to percentage of susceptible pupils infected in that generation period, i.e., week and half. Center of largest link indicates number of susceptible pupils sharing ventilation at peak of epidemic when generations begin to decline, thus locating threshold sanitary ventilation per susceptible pupil. Chart on which chains are constructed described in Dynamics of Air-Borne Infection, *Am. J. M. Sc.*, 206:11-17 (July), 1943.

of a second generation. This linkage of cases in one generation to infectors of the next forges the chains of successive generations illustrated on Chart 1.

Obviously while cases exceed infectors rS is greater than unity and generations are growing, reach a "steady state" at the peak of the epidemic when $rS_T = 1$, and decline when infectors exceed cases, or rS falls below unity. The "density" of susceptible persons, S_T , at the epidemic peak, or the reciprocal of the effective contact rate, is called the "threshold," because if this "density" is not maintained by accession of persons susceptible to the disease, as when contagion becomes endemic, cases are sporadic and the disease dies out. During an epidemic the "density" theoretically falls as far below as it started above the "threshold," though our school results seem to indicate a proportional rather than an absolute relationship.⁹

To one accustomed to the erratic behavior of measles in classes such an orderly array may seem unrealistic, yet the diagonal on Chart 2, approximating the computed total infections for classes of differing susceptibility, portrays diagrammatically the pregnant fact that the percentage of susceptible pupils who contract the disease when introduced into classes increases with the number of susceptible children in the classrooms. The reality of this fact is indicated by the percentage of susceptible pupils in different grades of a large centralized school near Syracuse who contracted measles during a recent epidemic.¹⁰ With enrolled classes of 33 pupils (an approximate average) the numbers plotted on the chart correspond with percentages of susceptible children in the grades. Since the cases contracted outside the classroom are included in these data, the plotted number of cases per 100 susceptible children exceeds somewhat the number resulting only from dynamic spread of measles

within the classroom. Nevertheless it becomes evident that "crowding" is a major factor in the contagiousness of measles.

SANITARY VENTILATION

Now in terms of droplet nuclei infection, S is proportional to the amount of infected air breathed by susceptible persons; I to the amount of infection contributed to the air by the previous generation of cases; and r to the dilution of infection afforded by ventilation, or to the reciprocal of V/S , where V represents ventilation per susceptible occupant (Chart 1). The substitution of these factors has proved the basic equation of the law of mass action to apply in quantitative experimental air-

CHART 2—Increasing Percentage of Susceptible Pupils Who Develop Measles as Number of Susceptible Pupils per Classroom Increases

Diagonal approximates percentage computed with 10 per cent effective contact rate per generation. Marked circles indicate percentage of susceptible pupils in primary grades of Mexico School who developed measles in 1946 epidemic (10). Percentage of susceptible pupils corresponds to 33 pupils per class (approximate average).

borne tuberculosis in rabbits.¹¹ Since rS_T becomes unity at "threshold density of susceptibles," ventilation per susceptible occupant at this "density," V_T , becomes the natural sanitary unit of ventilation and the law of mass action, as applied to air-borne contagion, then becomes $CV = IV_T$. Only below threshold ventilation, or when V is less than V_T , can droplet nuclei contagion become epidemic; cases are sporadic when V exceeds V_T , and the infection dies out.

Ventilation is usually expressed as cubic feet of fresh air replacement, or cubic feet per occupant—per susceptible occupant in sanitary ventilation. Sometimes it is more convenient to express ventilation in air changes of confined atmospheres, and if a *lethe* of disinfection is defined as the bactericidal equivalent of bacterial removal by dilution with one air change (one volume pure air replacement with continuous mixing), sanitary ventilation by air disinfection can be expressed in cubic foot-lethes.¹² By principles underlying these transformations elaborated elsewhere,² sanitary ventilation can be measured bacteriologically by the equilibrium concentration of standard test organisms, atomized at a constant rate into an enclosed atmosphere at representative locations, determined at another representative location with and without air disinfection. Multiplying the die-away rate without disinfection by the ratio of equilibrium concentrations gives *lethes*, or equivalent air changes.

Radiant disinfection of air in primary schools has played a dominant role in the experimental study of sanitary ventilation. The number of air-suspended bacteria killed by irradiation of a dry confined atmosphere can theoretically be deduced from a generalized hypothesis combining three accepted laws: the inverse square law of radiant intensity; the Roscoe-Bunsen law of

reciprocity of time and identity of exposure; and the quantum (logarithmic) law of disinfection.¹³ By this hypothesis the number killed becomes proportional to the number of photons, or to ergs of radiant energy intercepted by living bacteria. If a ray be regarded as a constant stream of photons, then the number of photons in a confined atmosphere is proportional to the total lengths of the rays between the points of entrance and disappearance from the enclosed space. Dividing the volume of the room into this total length, or the sum of the products of the rays into their length, gives average intensity. Thus, radiation in watts multiplied by average ray length in feet gives total irradiation in foot-watts which, divided by room volume in cubic feet gives average intensity in watts per square foot.

This reciprocal relationship between radiant flux and distance traversed through an enclosed space is obvious with uniform light intensity. Thus, one watt of uniform parallel light, such as sunlight, traversing 10 feet of a transparent column 10 feet long and of 1 square foot cross-section, will irradiate 10 cubic feet to 10 foot-watts, or 1 foot-watt per cubic foot, giving an intensity of 1 watt per square foot. In like manner, 10 watts falling perpendicularly upon 10 square feet of a side, passing through 1 foot of this column, will also irradiate 10 cubic feet of air to 10 foot-watts, giving average intensity of 1 watt per square foot. In any position or in any form, 10 cubic feet would be irradiated by 10 foot-watts, the product of the flux into mean ray length. Regardless of the form of the space or the direction of the rays, irradiation is given by radiant flux multiplied by mean ray length.¹⁴

It follows from the generalized law of radiant disinfection that the greatest number of organisms suspended in a given volume of air are killed when uni-

formly exposed to a given amount of irradiation, the lethal efficiency of uniform irradiation therefore being a maximum. We were unable to irradiate large spaces uniformly but were able to devise a chamber providing uniform exposure to a point source at the center, toward which air flowed with a velocity inversely proportional to the square of the distance from the source. The product of time and intensity of exposure of air-borne organisms to the source was therefore constant at any point, and the determined foot-lethes divided by computed foot-watt minutes of exposure, or the product of average intensity by time of exposure, gave the lethal equivalent of irradiation. Against standard bacterial suspension in dry air 0.002 foot-watt minutes of irradiation in the 2537Å wave band was equivalent to a cubic foot-lethe, less than a tenth of the irradiation required in humid air, on moist agar surfaces, or in aqueous suspension.¹⁵ If radiation in this wave band be adopted as standard lethal radiation, then a foot-watt minute of standard uniform lethal irradiation is equivalent to 500 cubic foot-lethes of standard air disinfection, or cubic feet of sanitary ventilation.

But it is not feasible to irradiate the occupied zone of a room to the desired average intensity; and, so, irradiation efficiency in practice depends upon design. Generally the amount of irradiation realized from a radiant source in an enclosed space depends directly upon mean ray length; the uniformity of irradiation of the space normally increases with mean ray length, the uniformity of exposure depending upon air circulation usually increases as rays are lengthened; and the disinfection of organisms en route from occupant to occupant approaches average disinfection as rays are lengthened. The hygienic rating of disinfection thus increases *inter alia* with mean ray length.¹³

The role of air circulation in equal-

izing exposure of air-borne organisms to differing intensity in ventilated spaces is little appreciated by those who have not measured radiant disinfection by bacteriologic procedures. With good design, air circulation between the occupied and upper irradiated zone, expressed in terms of the amount of recirculation of the air through a chamber uniformly irradiated with the given number of foot-watts exceeded three air changes per minute. Thus, by radiant disinfection with 6 foot-watts per pupil, more than twenty times the sanitary equivalent of standard school ventilation—exceeding threshold sanitary ventilation (Chart 1)—has been attained in experimental schools.¹⁶

DYNAMIC EXPERIMENT

Measles epidemics would not propagate in these schools according to the dynamic hypothesis discussed above. Records^{17,16, 4, 6 *} of nine years' experience in the irradiated Primary Department of the Germantown Friends School and six in the two Swarthmore Primary Schools, as compared with four years' experience in the unirradiated Primary Department of the William Penn Charter School and the two Nether Providence Primary Schools, indicate that:

1. The effective contact rate of measles in classrooms was reduced; per hundred susceptible classmates of a pupil becoming ill with measles while attending class (unit of exposure) 11.0 contracted the disease in unirradiated schools, during the second following week, as against 3.1 in irradiated schools.

2. The dynamic spread of the measles in the school was checked; per hundred susceptible pupils of unirradiated schools more than twice, and in classrooms more than five times, as many were infected.

3. The community threshold for primary school children was raised; per hundred pupils in unirradiated primary schools, half again as many had had measles.

* Note: presented on slides at the meeting but omitted on editorial grounds.

Q Fever in Los Angeles County

Description of Some of Its Epidemiological Features

CHARLES C. SHEPARD, M.D., AND
ROBERT J. HUEBNER, M.D.

Division of Infectious Diseases, National Institute of Health, Bethesda, Md.

Q FEVER has been found to occur in Los Angeles County, California, in an apparently endemic fashion, and this paper describes certain characteristics of the disease in that area.

Two naturally occurring outbreaks of Q fever are known to have taken place in the United States. The first appeared in Amarillo, Tex., in March, 1946,¹ and the second in Chicago, Ill., in August, 1946.² These two epidemics were alike in many respects; both were sharp outbreaks arising from occupational exposure of susceptible persons to stock being slaughtered or moving to slaughter. The attack rates were high in both instances, being over 50 per cent in the most heavily exposed groups, and the dates of onset of the cases were distributed over a 2 to 3 week period, the variation being chiefly accounted for by the spread in incubation period of the human disease.

It seemed clear from studies of the two outbreaks that infected cattle in Amarillo and infected calves or sheep in Chicago had been the source of human infection, and that transmission to slaughter-house workers had come from infected tissues and body fluids either by direct contact or by means of droplets of splattered fluids. Ticks had been very rarely seen on animals in either of these locations, and, in Chicago, cases did not tend to develop in persons associated with operations on hides, but instead were concentrated in personnel handling viscera.

Although the means by which the human beings had become infected was somewhat clarified by these studies, the manner of infection of the animals was not obvious, and it was not possible to gain a clear picture of the natural reservoirs of the disease in this country. For one reason the infectious source had long since been removed when the outbreaks occurred, and the epidemiological investigations were necessarily retrospective. The endemic area now found in Los Angeles County appears to provide suitable material for investigation of the natural reservoir problem.

The apparent lack of an insect vector in the two American outbreaks and their explosive and isolated nature seems to be different from the picture in Australia.³

THE OUTBREAK IN LOS ANGELES COUNTY *General Description of Area—*

The cases which have been found have developed in the milk shed area of Los Angeles County. This zone is in flat land 10-30 miles southeast of the center of the city of Los Angeles. The climate is warm and dry and moderated considerably by the Pacific Ocean.*

This dairy area is one of the most concentrated in the world. There is

* Weather bureau records show that in Los Angeles since 1877 the average yearly rainfall has totaled 15.55 inches with 14.22 inches of this falling in the months from November through March. The average temperature for the same period has been 63.0° F. with monthly means varying from 55.6° in January to 71.4° in August. In 1946 the highest temperature was 95° and the lowest 38°.

TABLE 1
Human Cases of Q Fever

| No. | Age | Sex | Pneumonitis | Days of Fever | Date of Onset | Complement-Fixation titer | Date Sample taken | Remarks |
|-----|-----|-----|---|---------------|---------------|---------------------------|-------------------|---|
| 1 | 62 | F | By x-ray | ? | 11-20 | 128 | 5-25 | No definite exposure to dairies recalled. |
| 2 | 51 | M | By x-ray | 11 | 11-25 | 128 | 6-7 | Had visited small farms. |
| 3 | 31 | M | By x-ray | 21 | 12-28 | 128 | 5-27 | Visited dairy occasionally. |
| 4 | 35 | M | By x-ray | 10 | 2-6 | 128 | 4-28 | Visited dairies frequently. |
| 5 | 29 | M | By x-ray | 9 | 2-11 | 256 | 5-26 | Visited dairy about 3 weeks before onset. |
| 6 | 15 | M | Physical findings and bloody sputum | 21 | 2-23 | 512 | 4-28 | Frequently played around dairy. |
| 7 | 45 | M | Physical findings | 6 | 4-6 | 64 | 5-21 | Had visited dairies. |
| 8 | 32 | F | Physical findings and bloody sputum | 10 | 4-13 | 512 | 4-28 | Home 100 yards from several dairies. |
| 9 | 27 | F | By x-ray | 12 | 4-20 | 512 | 6-4 | Home 100 yards from dairy. |
| 10 | 30 | M | By x-ray | 12 | 4-24 | 128 | 5-22 | Two dairies across street. |
| 11 | 28 | M | By x-ray | 11 | 4-26 | 0 | 4-30 | Visited dairy 127 days before onset. |
| 12 | 50 | M | By x-ray | 12 | 5-1 | 128 | 5-21 | Cows kept in field beside house. |
| 13 | 35 | F | Physical findings | 6 | 5-10 | 64 | 5-17 | Home 200 yards from dairy. |
| 14 | 36 | M | Physical findings | 7 | 5-14 | 128 | 5-21 | |
| 15 | 26 | F | No x-ray. No physical findings of pneumonitis | 10 | 5-15 | 0 | 5-16 | No definite exposure to dairies recalled. |
| | | | | | | 512 | 6-5 | |
| | | | | | | 4 | 5-23 | Wife of Case No. 10. |
| | | | | | | 512 | 6-4 | |
| 16- | 30 | M | By x-ray | 3 | 5-20 | 0 | 5-26 | Home 100 yards from several dairies. |
| 17 | 39 | M | By x-ray | 10 | 5-22 | 512 | 6-5 | |
| | | | | | | 0 | 5-28 | Home surrounded by dairy pens. |
| | | | | | | 128 | 6-2 | |
| | | | | | | 128 | 6-9 | |

as has been described by others. The onset was acute with fever, headache, chills or chilly sensations, and body aches and pains. Cough was frequently complained of but was not a prominent symptom. The sputum which was sometimes produced was at times blood-tinged. Chest pain was common and was usually of a lateral distribution, although a feeling of substernal congestion was frequent. Physical examination of the chest often revealed little of note except perhaps suggestive findings. Respirations were elevated when pneumonic involvement was extensive. Roentgenography revealed a pneumonic process which was usually diagnosed as "atypical" pneumonia when patchy, and "early lobar" pneumonia when diffuse. The leucocyte count tended to be normal or slightly elevated. The illness ran a course of 1 to 3 weeks' fever with

prolonged convalescence especially in older patients. No deaths were found which could be attributed to Q fever.

Many of the patients had recovered when first visited and the criteria of diagnosis had then to be a typical clinical history and the presence of specific complement-fixing antibodies. When patients were seen in the acute stage, blood was obtained, so that a rise in antibody titer could be shown with a later specimen. In addition the clot from the acute stage blood was inoculated into guinea pigs in an attempt to isolate *R. burneti*. It is felt that the diagnosis was firmly established by the demonstration of a marked rise in antibody during the illness or by the isolation of the etiologic agents.

Isolation of *R. Burneti* into guinea pigs was successful in cases No. 8, 11, 14, and 16. The strains were also es-

their antibodies in the course of their work, the results indicate the rate of exposure, since some of them had developed antibodies in less than one year's experience. The dairy workers with negative sera could have become so after having been positive at an earlier date, so that it is possible that more of them had been positive at one time or another. We have observed that after laboratory-acquired Q fever in human beings the sera revert to negative in the course of several years.

Table 3 shows the complement-fixation results with sera gathered from persons who had been ill with diseases which were presumably not Q fever. Although they gave histories of upper respiratory infections, blood samples were obtained and their sera were examined for Q fever antibodies. Though the number is small, the results show that sera of people living near the dairies, but not in actual contact with the cows may also show Q fever antibodies. Some of those with positive serology said they had never visited the dairy near which they lived.

In Table 4 are shown the results on sera obtained from the Los Angeles County and the District of Columbia laboratories. They were in both cases routine sera found negative in serologic tests for syphilis. Those from Los Angeles County were selected because the donor's residence had been given in the general milk shed area. Actually most people living in this area do not

live close to the dairies, since the human population is concentrated in towns, and the dairies are for the most part distributed about the countryside. Of the 166 specimens examined, 5 were found positive in low dilution. The 96 sera from the District of Columbia were all negative. The incidence of positive sera from the Los Angeles County milk shed is low, .3.0 per cent, but none were expected from previous experience.

The results of Tables 2, 3, and 4, when considered together, show that positive complement-fixations for Q fever can be expected in this area on sera of persons not undergoing obvious attacks of Q fever. Although some of the persons with positive sera were not questioned about previous illness, many were questioned at some length, and no definite history of Q fever could be obtained.

Serologic Studies on Sera of Cows—

We have previously examined, by the complement-fixation test for Q fever, bovine sera from two general areas. Nearly sixty sera of beef cattle from Texas and states adjacent to the Texas Panhandle were found negative last year, and more than sixty sera from Maryland milk cows were found negative at the same time.

It was possible to sample the cows at 9 different dairies in the Los Angeles milk shed area and to study the blood sera for complement-fixing antibodies for Q fever. The dairies were distributed across the milk shed area. Table 5

TABLE 5

Complement-fixation Results on Sera of Cows from Several Dairies in Area

| Dairy No. | Number of sera | Number Negative | Number Positive | End Titers | | | | | | |

gives the results. In all, 130 sera were examined and 21 were found positive, 10 of them in dilutions of 1:64 or higher. The incidence of positives, 16.2 per cent, found in this survey varied from one dairy to another and was highest in dairy E and lowest in dairy A. The significance of the difference in the rates is probably not great, and there was some evidence that Q fever infection was present in all of them. For example, in dairy A several of the dairy workers were found to have positive sera. Other dairy workers of Table 2 were employed at dairies E, F, G, H, and I, and the patient in Case 11 visited dairy I 27 days before he became ill.

DISCUSSION

Although only 17 cases are listed in Table 1, it is likely that many more cases have occurred in the Los Angeles area. The complete reporting of Q fever must depend upon increased awareness of its presence by the physicians of the area, and the adequate use of laboratory diagnostic facilities. Most of the persons listed in Table 1 were patients of a few physicians who were especially interested in discovering cases.

The patients listed in Table 1 as having undergone clinical illness with Q fever did not have intimate contact with cows, and this point merits comment since it tends to cause confusion. Many people deny contact with cows except when they have touched them. As has been stated the "contact" of the persons in Table 1 arose from their living near dairies or having visited them within the incubation period of the disease.

None of the clinical cases found developed in dairy workers, yet evidence for the frequent infection of dairy workers was obtained by serological studies. Half of the 20 dairy workers sampled showed complement-fixing antibodies for Q fever rickettsiae, and it seems likely that others of them had been in-

fectured at one time or another, since positive to negative conversion may take place within a few years. Many of those having antibodies for Q fever did not give histories of illness particularly suggestive of Q fever. It thus appears that the dairy workers had undergone mild or inapparent attacks of Q fever. Mild attacks are known to occur.^{2, 6, 7, 8}

An apparent inconsistency arises from these considerations, that is, the persons with what was apparently the greatest exposure seemed to escape clinical illness. This situation could have arisen from sampling methods, since if mild Q fever were common and severe Q fever rare in this area, and if exposure to the disease were not too greatly concentrated in the dairy workers, the severe cases could have been found in non-dairy workers simply because of their numerical superiority. An alternative explanation also appears possible, namely, that the exposure of the dairy workers is such that it tends to result in the mild disease rather than the severe form.

The complement-fixation results in Tables 2, 3, and 4 indicate that there has been considerable past exposure to Q fever in certain groups of persons in this area. This has apparently resulted in immunity in many cases. In addition it gives rise to difficulties in making a definite diagnosis of Q fever in a particular illness, since the demonstration of complement-fixing antibodies for Q fever rickettsiae in a single specimen taken in the course of a febrile illness is not sufficient to establish the etiology of the fever as being *R. burneti*. In this study, in order to investigate illness which had taken place in the near past we made the diagnosis of Q fever on a single positive serum when the patient had undergone an attack of "atypical" pneumonia. However, whenever the patient could be seen in the acute stage, a sample of blood was taken then, thus making it possible to establish the diagnosis of Q fever with considerable cer-

tainty by demonstrating a rise in antibody in the course of the disease, or by isolating *R. burneti* from the patient's blood, or by both means.

Q fever in the cows of this area appears to be common as judged by the results of the complement-fixation test. It does not appear possible to state definitely that the cows are the source of human Q fever infection since the possibility remains that the same source infected both cows and human beings.

The origin of most of the cattle in other regions suggests the possibility that the infection giving rise to the positive complement-fixations might have been acquired outside the Los Angeles area. However, 3 of the cows positive by complement-fixation were born and raised in the area; their titers were all low (1:8), but such titers seem to be significant, since the cow sera studied heretofore have been completely negative.

The negative results with bovine sera from the Texas Panhandle and adjacent areas and from Maryland were obtained in the course of investigations of an agglutination test using *R. burneti* suspensions as test antigen. Derrick, Smith, and Brown have reported 13 of 879 Australian dairy cows showing agglutinins for Q fever.⁹ However, the agglutination test as we performed it appeared unreliable and of 500-600 bovine sera studied about 60 per cent gave positive agglutination tests. We concluded that the agglutination results we saw were most likely nonspecific and not related to past infection with *R. burneti*.

It would be of interest to know when Q fever infection appeared in Los Angeles County, but it seems that we have little evidence on this point. The first case of Q fever in Table 1 was in a patient whose illness started November, 1946. It is quite possible that cases have been occurring for some time, and it is doubtful if the presence of infection would have become known now had it not been for the recent interest in Q

fever because of outbreaks elsewhere in the country.

It should be noted that few if any ticks are present on the cows in the Los Angeles milk shed, and that the fly population is kept low by DDT spraying of barns and the frequent removal of manure.

SUMMARY

1. Q fever has been found occurring in an apparently endemic manner in the milk shed area of Los Angeles County. Most of the cases lived near or visited dairies.

2. Serological studies revealed that many people who did not give histories of clinical attacks of Q fever showed complement-fixing antibodies for Q fever. Half of the dairy workers and people living near dairies showed specific antibodies.

3. Of 130 sera of cows in the area 21 showed antibodies for Q fever, some in high titer.

ACKNOWLEDGMENT—Acknowledgment must be made of our indebtedness to many people in the course of this work. Frank W. Young, M.D., of Artesia, Calif., suspected Q fever on a clinical basis and sent us a number of sera, many of which were positive by complement-fixation, and it was in this way that the

presence of Q fever in the area was discovered.

Much help was freely given by the personnel of the Los Angeles County Health Department. The coöperation of the local physicians is greatly appreciated, as is the assistance of the dairy owners.

ADDENDUM

Since this paper was submitted for publication, Huebner, Jellison, Beck, Parker, and Shepard have published the results of further

investigations at Los Angeles. *Pub Health Rep.*, 63:201 (Feb. 13), 1948.

They report the finding of *R. burneti*, the causative agent of Q Fever, in the raw milk of 4 dairies in Southern California. Pasteurization results under field conditions, while incomplete, apparently rendered naturally infected milk non-infectious for guinea pigs. Available epidemiological evidence does not indicate that the drinking of milk was the cause of a majority of the cases thus far studied.

Silver Nitrate Still the Preferred Drug in Ophthalmia Neonatorum

In the April issue of the *Woman's Home Companion*, Miriam Zeller Gross, in an article entitled, "Can Present Laws Blind Your Baby?" proposed that the use of silver nitrate be discarded as a method of preventing the infection of eyes of the new-born. She proposes that penicillin be substituted because of its proved value and proved harmlessness.

Among the protests of the scientific accuracy of the article is a report released by the New York Academy of Medicine, on request for an opinion by the Commissioner of Health of New York City. He had some months ago asked the opinion of the Academy about the wisdom of amending the New York City Sanitary Code requirements for silver nitrate.

A digest of Academy opinion follows:

In preventing infection of the baby at birth, both penicillin and silver

nitrate are safe to use when the solutions are prepared carefully and applied properly, a committee of specialists reported. There is no evidence that 1 per cent or even 2 per cent solutions of silver nitrate, which are those used in the prophylaxis of ophthalmia neonatorum, have ever damaged vision.

Bacteria that cause gonorrhea and pneumonia are most likely to cause blindness in the baby, and the concentration of penicillin most effective to halt the growth of these bacteria is not yet known.

In view of the present available evidence of the relative effectiveness of silver nitrate, silver acetate, and penicillin in the control of ophthalmia neonatorum, it would seem that existing laws requiring the use of silver nitrate should not at the present time be revised by the substitution of penicillin for silver nitrate.

Relative Efficiency of the Open and the Confidential Method of Reporting Causes of Death*

PAUL H. JACOBSON

Vital Statistics Analyst, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

SINCE January 1, 1947, the confidential method of reporting deaths from natural causes has been in use in all five boroughs of New York City. The system had been tried on an experimental basis in the borough of Manhattan during the preceding eight years. The legal and ethical bases for the use of the confidential certificate have been previously reported.¹

Primarily on these bases but also because of its approval by the Committee on Public Health Relations of the New York Academy of Medicine and the five county medical societies of the city, the method was extended to all boroughs. During the first few years of its use in Manhattan, there appeared to be some indications of its statistical superiority,

but no scientific study had been made by means of which its relative efficiency could be impartially evaluated. Accordingly, in November, 1942, Dr. Ernest L. Stebbins, then Commissioner of Health, secured a grant from the New York Foundation for the purpose of making such a study.

HISTORY OF DEATH CERTIFICATION

The registration of causes of death originated with a view to controlling the spread of pestilences, and from the start the statistics of death, by cause, have served as a basis for public health activities. Because of this fact, the registration of vital events in the United States has generally been made a function of state and local health departments.

The ethical aspects of medical certification have been the subject of controversy to a much greater extent in Europe than in the United States. In some countries of Europe, this controversy resulted in the refusal of the attending physician to participate in the reporting of a death or the cause thereof. Switzerland has been a notable exception. More than a half century ago, the Swiss developed a confidential method of reporting causes of death which gave the public authorities information essential to the protection of the public health and at the same time guaranteed the preservation of professional secrets.

In the United States, little if any con-

* This paper presents the findings of the study made by the New York City Department of Health in 1943-1944. The study was carried on under the direction of the late Thomas J. Duffield and the author, with the assistance of Marjorie T. Bellows, Louis Weiner, and their staffs in the Bureau of Records and Statistics. A Statistical Advisory Committee guided the department in the conduct of the study and in the appraisal of the results. The committee consisted of the following members:

Ernest L. Stebbins, M.D., Commissioner of Health, Chairman

Alfred Angrist, M.D., Pathologist, Jewish Memorial and Queens General Hospitals

E. H. L. Corwin, Ph.D., Executive Secretary, Committee on Public Health Relations, New York Academy of Medicine

Godias J. Drolet, Statistician and Assistant Director, New York Tuberculosis and Health Association

Haven Emerson, M.D., Emeritus Professor of Public Health Practice, Columbia University, and Member, Board of Health

John W. Fertig, Ph.D., Professor of Biostatistics, Columbia University

Hugo Muench, M.D., Fellowship Adviser. of The Rockefeller Foundation

sideration was given to the question of the confidential nature of medical diagnoses until recent years. A start toward evaluating the problem in this country was made in 1933-1934 when Nicoll and Bellows² showed that syphilis and alcoholism were understated in the Westchester County, New York, mortality statistics. A voluntary system of confidential reporting, which they instituted, was discontinued after several months when found unsatisfactory.³

METHODS OF REPORTING CAUSES OF DEATH

There are two fundamental methods by which causes of death may be reported: (a) the open method, and (b) the confidential method.

(a) *The Open Method*—In the United States, it is the general practice to report deaths on a certificate which requires the following: (i) the name of the deceased, (ii) personal particulars identifying the deceased, (iii) the medical certificate of death, and (iv) information regarding the date and place of burial or cremation. In the medical certificate of death, the physician is expected to state the period of his attendance upon the deceased, the medical diagnoses of the principal and contributory causes of death, the duration of those conditions, autopsy findings, and operations performed.

(b) *The Confidential Method*—In an effort to improve the method of reporting, and at the same time to preserve the essential features of the American procedures, the late Thomas J. Duffield, then Registrar of Records in New York City, in 1936 proposed a confidential system of death certification. After considerable discussion, the Board of Health approved the introduction of the Physician's Confidential Medical Report as an experiment in the borough of Manhattan, commencing January 1, 1939.* Previously, in the entire city, the open form was used, and this form or a similar

one was used in the other four boroughs through December 31, 1946.

Objections to the open form, which are overcome by the confidential certificate, arise from the fact that it has become the practice of custodians of vital records in the United States, as elsewhere, to issue copies of official records of death to relatives for use in the settlement of the affairs of the deceased.

In New York City, for more than a quarter of a century, the certified copies of death certificates issued by the Department of Health have been negative photostatic reproductions of the face of the certificate. Under such circumstances, it is possible that physicians, in keeping with their feelings regarding the ethics of their profession and the law governing professional secrecy, have not always recorded the complete diagnosis of the cause of death to the best of their knowledge and belief. The primary reason for withholding information appears to be the fact that the family physician may not wish to record a diagnosis which offends survivors because it reflects unfavorably upon the memory of the deceased.^{2,3} The fact that a death certificate is of access on legal order and that a copy may be required for the settlement of the estate of the deceased are not thought to be nearly so important in promoting incomplete reporting.† Regardless of the reasons, in stating anything less than the full truth, physicians withhold information that may be im-

* The confidential method, at that time, was also used by Switzerland, and by the cities of Nürnberg, the Hague, and Amsterdam, and to a certain extent in England and Wales⁴; it has since been put into use by the Province of Quebec, Canada.^{5,6}

† The experience of one large insurance company has consistently shown that physicians have no intent to withhold information which can be used for scientific or statistical purposes. A comprehensive published report for their 1911-1914 experience revealed that through supplementary inquiries to physicians the number of deaths attributed to such significant titles as alcoholism, syphilis, and gonococcus infection were increased by 21, 78, and 130 per cent, respectively.⁷ Similar results are evident from unpublished data for recent years.

portant in the planning and administration of public health and related programs.

With the confidential form of reporting, a copy of a death record includes only the following: (i) the name of the deceased; (ii) personal particulars identifying the deceased; (iii) certification that the death occurred on a given date and was due to natural causes, and (iv) information regarding the date and place of burial or cremation. No part of the Physician's Confidential Medical Report, including the causes of death, duration of diseases, and related information appears on the copy of the death record issued to relatives of the deceased. Thus the contents of the confidential medical report are not divulged.

PLAN OF THE SURVEY

In 1943 the Department of Health initiated a study, jointly sponsored by the Department of Hospitals, to evaluate the comparative statistical efficiency of the two methods of reporting causes of death in New York City. A pilot study of 955 deaths which occurred in municipal hospitals in 1941 was completed in the early months of 1943. On the basis of these preliminary statistics, the final plan for the study was formulated, and collection of data started on July 1, 1943.

Objective—The objective of the study was to ascertain whether the confidential method of reporting causes of death resulted in statements of cause of death more nearly in agreement with the physician's knowledge and belief at the time the certificate was filled in than did the open method. It should be noted that the study was not concerned with the accuracy of a physician's knowledge. No method of reporting is able to eliminate diagnostic errors which result from limited clinical examination or medical knowledge; for example, cases in which no operation, biopsy, or other special laboratory tests are performed.*

Criterion—Not all discrepancies between what the physician knows and what he actually records on the death certificate are due to wilful alteration of the known facts. Carelessness, lack of uniformity of definition of terms, and personal interpretation of their meaning are important factors contributing to such differences.¹⁰⁻¹³ To some extent, these differences may be minimized by education and by proper formulation of the questions on death certificates.^{14, 15} Some of these errors were eliminated from the study, by classifying the various individual titles of the 1938 revision of the *International List* into 17 diagnostic groups. Thus only changes from one group to another were considered significant.

In consideration of the above factors, the basic criterion of the study was established as the *correlation between the primary cause of death selected from the statement of cause of death reported to the Department of Health and the primary cause selected from the diagnoses abstracted from the medical case history* (selected and coded according to the *Manual of the International List of Causes of Death*, Fifth Revision, and *Joint Causes of Death*, Fourth Edition, 1939).

The secondary criterion consists of comparison of the relative frequency with which the following seven conditions (existing or preëxisting) were mentioned anywhere in the case history and on the death certificate: (a) alcoholism, (b) cancer, (c) diabetes mellitus, (d) mental disease, (e) puerperal sepsis, (f) syphilis, and (g) tuberculosis.

The latter criterion was adopted since it appeared desirable to ascertain the relative completeness with which statements are made on the two certifi-

* Because of the deficiencies in clinical diagnoses as revealed by comparisons with autopsy findings,^{8, 9} since June 1, 1947, all autopsy findings for deaths which occur in New York City are reported to the Department of Health on a supplementary confidential medical report.

cates. For example, mental disease is rarely the primary cause of death, but is it more accurately reported as a contributory or associated cause on the confidential death certificate than on the open? Moreover, a sub-sample of 89 cases, independently abstracted by four medical workers, indicated that any method of analysis must assume an indeterminate difference in the primary cause of death due solely to the process of abstraction (individual differences of opinion, etc.). Personal variations are practically eliminated from the data obtained for the conditions specified above (check list). However, if any findings in favor of the confidential certificate are disclosed by these data and not from those on the primary cause of death, they cannot be conclusively attributed to the method of certification. This arises from the fact that the Physician's Confidential Medical Report provides more space for recording the statement of cause of death than does the open certificate.

Selection of Sample—Approximately 28 per cent of the deaths in New York City occur among persons who receive medical attention prior to death and who die at home. These cases afford the best example of the physician-family relationship and might be expected to provide fruitful information for evaluating the efficiency of the confidential certificate. However, no objective method is available for analyzing these cause-of-death statements. The difficulty arises primarily from the fact that case histories in the private practitioner's office are highly incomplete, lack uniformity, or are nonexistent.* As a result, the proprietary hospitals were selected for study, since the role of the physician in these hospitals most closely approximates that of the private practitioner. In contrast, physicians in municipal hospitals do not have such close personal relationship with their patients. It was expected, therefore, that

differences due to wilful alteration of the known facts would not be as great for municipal as for proprietary hospitals. Thus the municipal hospitals were included in the study to serve as a means of interpreting the findings for the proprietary hospitals.†

All proprietary hospitals licensed by the General Inspector's Office of the Department of Hospitals on July 1, 1943, which had been in operation during 1937-1939 and 1941, the period covered by the study, were included in the sample. Nine hospitals — Bellevue, Harlem, City, New York Cancer, and Goldwater Memorial in the borough of Manhattan, and Coney Island, Kings County, Queens General, and Lincoln in other boroughs—were selected for study of municipal hospitals; restricted, however, to deaths reported during January and February of the study years. Because of the small number of deaths involved, the borough of Richmond was not included in the study.

Each borough office of the Department of Health maintains a cross-index file by place of death for all deaths which are reported within the borough. The deaths which occurred in the hospitals selected for study were easily identified from these files. Cases certified by the medical examiner's office were then eliminated by inspection of the death certificates.

Procedure—The Department of Hospitals, which by law is authorized to license and to control the practices of proprietary hospitals, was most helpful in securing access to the hospital records. Dr. Edward M. Bernecker, Commissioner of Hospitals, wrote to the

* The completeness with which syphilis and pulmonary tuberculosis are mentioned on these death certificates could be evaluated by checking the certificates for residents of the city against the department's rosters of known cases. Of much greater value for this and similar purposes, however, it would be desirable to add to the death certificate an item requesting the date and place of latest hospitalization (for deaths not occurring in institutions).

† Voluntary hospitals, which operate under approval of the State Department of Welfare, were not included in the study.

superintendent or proprietor of each hospital requesting his coöperation and explaining the purpose of the study. Each hospital was then contacted by the Department of Health, supplied with a list identifying the deceased included in the study, and appointments scheduled for the abstraction of the case histories.

A simple form was used to collect information; one copy was filled in for each death certificate and another for the corresponding hospital case history. The information was copied from the death certificate exactly as it was originally reported. Supplementary information in regard to causes of death, operations, special laboratory tests obtained through inquiries by burial desk clerks, nosologists, or from special autopsy reports, which is added to the back of the certificate, was not included as a part of the death certificate abstract. All of this work was carefully checked to detect clerical errors.

In preparing the abstracts of hospital case histories, the medical field worker was instructed to "assume that he is the physician called upon to fill out a death certificate and that his knowledge of the deceased is limited to the information found in the hospital case history." Only information available at the time the certificate was filled in was considered in recording the principal and contributory causes of death and using the check list. This information generally consisted of the final discharge diagnoses (excluding autopsy findings made available after the death certificate was executed*), results of laboratory tests, operations, observations during illness, and previous history. Since it was possible that knowledge of the

death certificate information might influence the abstractor in spite of all efforts to use unbiased judgment, the information from the hospital case history was abstracted onto a blank form, which was not collated with the death certificate abstract until each form had been individually processed and coded.

It was not practical or possible to verify the accuracy of all hospital case history abstracts. Moreover, it was recognized in planning the study that the abstractor's personal interpretation of the meaning and importance of conditions would have a significant bearing on his selection of the causes of death. Nevertheless, it was felt desirable to evaluate the completeness of the cause-of-death statements, including the check list data, and the frequency with which non-medical errors (use of incorrect chart, etc.) were committed. Accordingly, a sub-sample of cases from proprietary hospitals was checked by a Department of Health physician. Additional cases from both proprietary and municipal hospitals in which errors appeared possible were checked against the department's rosters of known syphilis and tuberculosis cases, or with responsible physicians in the hospitals in which the deaths occurred. Finally, all cases were reviewed by a physician of the department and questionable cases passed on by a physician of the Statistical Advisory Committee. Among the 7,330 abstracts of hospital case histories, several were adjusted by these methods. While not all errors may have been detected, it was evident that the data were sufficiently accurate for the purposes of the study.

COMPLETENESS AND REPRESENTATIVENESS OF THE DATA

A total of 15,000 cases was selected for study, 6,492 in proprietary hospitals, and 8,508 in municipal hospitals. Preference was given to completion of the work in proprietary hospitals, and

* It is recognized that it may not always have been possible to ascertain whether or not preliminary findings from autopsy were known to the physician at the time he signed the death certificate, especially in municipal hospitals. Analysis of the data, however, reveals no evidence of significant differences in the findings between autopsied and not autopsied cases.

as soon as the preliminary findings for these data were available, it was decided not to complete the abstraction of case histories in municipal hospitals. As a result, data for 1,678 deaths, or only one-fifth of the cases in municipal hospitals, were obtained for study. The great majority of these completed cases were Manhattan deaths which had been reported on the confidential certificate. The data from municipal hospitals, therefore, can be given little weight in this study. They are included in this report, however, since they appear to be consistent with the findings from proprietary hospitals.*

Of the 6,492 cases which were selected for study in proprietary hospitals, complete data were obtained for 5,652, the hospital charts could not be located for 715, and the charts for the remaining 125 could not be used because they contained insufficient information. According to their distribution by age, sex, color, and cause of death reported on the death certificate, the cases obtained for study from each borough and year comprise a representative sample of the cases originally selected.

MAJOR FINDINGS

The correlation between the primary causes of death as determined from diagnoses in hospital case histories and those determined from statements on death certificates for all 7,330 cases is shown in Table 1. These data indicate the causes to which deaths from selected conditions are generally attributed in New York City vital statistics. They also provide an approximate index of the extent to which these significant diseases are overstated or understated. These indices for the 17 cause-of-death

groups are given in Table 2; column 1 is computed from the data in Table 1, and the other columns from similar tabulations which could not be included in the space allotted for this paper.

The great concentration of cases in the diagonal cells in Table 1 means that there is a very substantial agreement between the diagnoses in hospital case histories and the statements of cause of death on death certificates, and that, judged by these broad cause-of-death groups, disagreement is the exception rather than the rule.

Of the 17 cause-of-death groups studied, only the *respiratory diseases* (33a, 104-114) appear to be significantly overstated in official mortality statistics. They were charged with an excess of 13 per cent in this sample (Table 2). The overreporting of these diseases, primarily the pneumonias, was especially marked among white persons whose deaths were certified by internes in municipal hospitals.

As may be seen from Table 1, many deaths due to respiratory diseases are charged to the cardiovascular-renal diseases and an even greater number due to the latter are incorrectly attributed to the former. The difficulty appears to arise both because of disagreement as to whether the condition is lobar or bronchopneumonia and equally as often from carelessness in stating "lobar" when "lobular" is meant, or vice versa. Since cardiovascular-renal diseases are frequently associated with pneumonia, under the *Joint Cause Manual*, the *International List* assignments for the former conditions are also affected by the proper determining factor as to the form of pneumonia. For example, a cardiovascular-renal condition associated with pneumonia is assigned to the former if lobular, but to the latter if lobar.

In contrast, five conditions (alcoholism, syphilis, puerperal infection, diabetes, and appendicitis) appear to be understated on death records. These

* Contrary to expectation, the data from municipal hospitals reveal greater variations than those from proprietary hospitals. This may result from the fact that quite frequently in municipal hospitals several physicians may attend the same patient, and often the physician who certifies the death may not have been previously connected with the case.

conditions will now be discussed.

Alcoholism (77,124a)—Of all conditions selected for study, alcoholism was most affected by differences between diagnoses in hospital case histories and causes of death stated on death certificates. Of the 54 deaths from alcoholism or alcoholic cirrhosis of the liver, only 23 (43 per cent) were so reported. Sixteen deaths were charged to other diseases of the digestive system, primarily cirrhosis of the liver without mention of alcoholism,* 7 to respiratory diseases, and the other 8 to various other causes. At the same time, 4 deaths supposedly due to other conditions were charged to alcoholism. In this sample, therefore, the official statistics accounted for only one-half of the mortality from alcoholism. This finding is in apparent agreement with the results

of the confidential inquiry in Westchester County, New York, which revealed that approximately three-fifths of the deaths from alcoholism in 1931-1933 were correctly charged.²

Did the confidential method of death certification, introduced in Manhattan in 1939, more accurately depict the mortality from alcoholism than the open method? The pertinent data are shown in Table 3. Since alcoholism is a relatively infrequent cause of death, only a small number of cases fell into the sample and the findings may be influenced by chance fluctuations. However, several facts are worthy of note. Approximately one-half of the deaths attributed to alcoholism were "improperly" reported from proprietary hospitals whether the open or confidential certificate was used. Even municipal hospitals in Manhattan understated this cause of death by one-half in 1939 and 1941. And, as may be seen from Table 2, this was also true for deaths certified by internes. Finally, it should be

* Today many physicians and pathologists question the role of alcohol in the causation of cirrhosis, as such. Thus, even though a patient with cirrhosis had a history of alcohol ingestion, they would prefer to place the etiology in the role of some dietary deficiency.

FIGURE 1

MORTALITY FROM SELECTED CAUSES MANHATTAN COMPARED WITH OTHER BOROUGHES OF NEW YORK CITY*

* By residence; non-residents included in borough of death.
 † To maintain comparability between the 1929 and 1938 revisions of the *International List*, deaths prior to 1940 are increased by 9.2 per cent for alcoholism and by 9.1 per cent for syphilis.

noted that, if alcoholism accounted for twice the number of deaths charged to it in official statistics, the recorded number of these deaths should increase significantly when the confidential certificate is used, if the method is more efficient than the open form of certification. Actually, as Figure 1 shows, the trend in Manhattan since 1938 has approximately paralleled the trend in the other boroughs.

Syphilis (30)—About the same extent of agreement between the hospital case history and the death certificate was found for syphilis as for alcoholism. Of the 141 deaths assigned to syphilis according to hospital records, only 66 (47 per cent) were so reported on death certificates. An additional 35 of these deaths were attributed to cardiovascular diseases, 13 to tuberculosis, and 27 to other causes (Table 1). In contrast, syphilis was selected as the primary

cause of death from 11 certificates for which the hospital charts charged the deaths to other conditions. Failure to note on the death certificate that syphilis was successfully treated accounted for some of these differences. Thus, only 55 per cent of the mortality from syphilis was reflected by the official statistics (Table 2). For syphilis as for alcoholism, the data confirm findings previously reported for Westchester County where the figure for syphilis was found to be 51 per cent.² Similar to the findings from that study, syphilis was more accurately reported as the primary cause of death for men than for women; in this study the ratio was 0.58 among white males and only 0.40 among white females.

Syphilis appears to have been more completely reported from proprietary hospitals in Manhattan during 1939 and 1941 than during 1937–1938 (Table 4):

charged to various other conditions. In contrast, the deaths of 22 persons were allocated to diabetes in disagreement with the facts recorded in their hospital case histories (Table 1). For the cases included in this study, therefore, only 86 per cent of the mortality from diabetes was stated in the official statistics (Table 2).

In view of the fact that diabetes was

less completely reported from proprietary than from municipal hospitals, and that deaths certified by attending physicians were least accurately recorded, one might expect an improvement with the use of the confidential certificate. No such evidence, however, is disclosed by the available data. As may be seen from Table 6, 78 per cent of the deaths due to diabetes in Manhattan proprie-

OTHER FINDINGS

Tuberculosis (13-22)—It does not appear probable from the data collected for this study that tuberculosis has been understated in the New York City mortality statistics for recent years. For every 100 deaths from tuberculosis according to hospital case histories, there were 101 assigned to the condition in the official death records (Tables 1 and 2). These findings are in apparent agreement with those obtained in the study in Williamson County, Tennessee.¹⁶

Although tuberculosis was not understated as the primary cause of death for the cases studied, its occurrence as a contributory cause was not completely recorded. This fact may be noted from a vertical comparison of the data in Table 8. For example, in Manhattan proprietary hospitals during 1937-1938, the extent of agreement was 100 per cent for tuberculosis as the primary cause of death, but only 90 per cent

for the condition as the primary or contributory cause. Regardless of the criterion used, however, there are no indications that tuberculosis was more efficiently recorded on the confidential than on the open certificate. The mortality statistics for New York City confirm this fact (Figure 1).

Cancer (45-55)—Of the seven conditions considered likely to be affected by confidential certification, cancer is both the most important and apparently the most completely reported. A study of deaths which occurred in Massachusetts in 1932¹⁷ revealed that approximately 6 per cent of the mortality from cancer was underreported on death certificates; 11 per cent of the cases were "missed" at the same time that 5 per cent were "overdiagnosed." More recently, from a survey of ten urban areas in 1937-1939, the U. S. Public Health Service reported that possibly only 5 per cent of the mortality from cancer was assigned to non-

quency of operations declined from 41.3 per cent in 1937 to 34.8 per cent in 1941, there was a slight improvement in reporting, from 96.6 per cent in 1937 to 98.2 per cent in 1941. This improvement, however, occurred in proprietary hospitals in boroughs other than Manhattan. Judged by proprietary hospital deaths, therefore, the confidential method did not result in more accurate reporting of operations.

DISCUSSION

When, about the year 1891, the confidential system of reporting was put into use in certain cantons of Switzerland, the number of reported deaths from syphilis was nearly doubled. Accordingly, the system was adopted and has been used throughout that country since January 1, 1901.¹⁹ On the basis of this experience, it was expected that there would be a marked increase in the reported mortality from syphilis, as well as from several other diseases, following the introduction of the confidential system to New York City. In the first year of its trial in Manhattan, the confidential report apparently had increased the accuracy with which the mortality from syphilis was reported. Since that time, however, the parallel trends in the mortality from the disease,

both in Manhattan and in the other boroughs of the city (Figure 1), have made it appear more probable that the rise, which was recorded in Manhattan from 1938 to 1939, was chiefly if not entirely a normal fluctuation.

The use of the confidential report was extended to the other four boroughs of the city on January 1, 1947. If the system proved effective, we should expect an increase in the mortality from alcoholism, syphilis, etc.; in these boroughs, but not in Manhattan, where no change in method of reporting occurred. The recorded mortality data for the first 11 months of 1947 compared with the same period of 1946, for seven conditions considered significant to confidential certification, are shown in Table 10. There is no evidence from those data of any changes which may be attributed to the system of reporting. Therefore, it may be concluded that, to date, the confidential report has had no significant effect on the accuracy of mortality statistics in New York City.

No method of reporting, of itself, can be expected to eliminate all of the factors which affect the accuracy of mortality statistics. In 1938, Dr. Halbert L. Dunn stated that "the errors in cause of death due to carelessness on the part of the physician in filling out the

TABLE 10

Mortality from Seven Selected Conditions in New York City, by Borough of Residence (non-residents included in borough of death), First Eleven Months of 1947 and 1946 compared

| Cause and International List Number | Number of Deaths | | | | Death Rate * | | | |
|--|------------------|-------|-----------------------|-------|--------------|-------|-----------------------|-------|
| | Manhattan | | All Other Boroughs | | Manhattan | | All Other Boroughs | |
| | 1947 | 1946 | 1947 | 1946 | 1947 | 1946 | 1947 | 1946 |

| Appendicitis (121) | 66 | 71 | 196 | 209 | 3.8 | 4.1 | 3.6 | 3.9 |

* Deaths from puerperal infection per 100,000 total births; all other causes per 100,000 total estimated population, adjusted to annual basis.

death certificate are probably fully as numerous as those arising from his desire for a confidential record. . . ."¹¹ From this study, one might add that simple ignorance of the rules of certification and lack of understanding of the mechanisms of death also have a greater bearing on the information that is recorded than does the method of reporting. Moreover, there are no indications that better statistics have resulted from the use of the confidential method.

How then may we effectively and efficiently improve the accuracy of mortality statistics? This is a problem of major importance which confronts the consumer of vital statistics. Together with the instructor in the medical school, he must devise a means of impressing the attending physician with the importance of his responsibility in reporting causes of death. This should involve careful perusal of the patient's history chart to determine the factors which caused and contributed to death, and entry of the cause-of-death statement on the certificate with sufficient accuracy and care so as to reflect his conclusions.* Some improvement could also be effected by a change in policy, in local health departments, from paper check-up by death certification clerks to a consultative service which the physician could call *before* he certifies the cause of death. This would enable the physician, who has had few deaths in

his own practice, to obtain the advice of one who has had practical experience with a great many cases as to the terminology and definition of causal mechanisms involved in a particular case.

The physician's unwillingness to record the causes of death to the best of his knowledge and belief is apparently of secondary importance to other factors which affect the accuracy of mortality statistics. Judged by the findings from this study, the confidential report does not improve the accuracy of diagnoses which reflect on the memory of the deceased. Apparently such improvement can be effected only through intensive educational campaigns which impress both the medical profession and the public with the fact that the development of medical knowledge, and the ability to combat disease, are dependent upon complete and accurate statistics. The campaigns against tuberculosis and cancer have removed many of the barriers of fear and superstition concerning these conditions and have thus been a factor in the present state of completeness with which they are recorded on death certificates. The current campaign against the venereal diseases has already effected a reduction in the inaccuracy of these mortality statistics. In the near future, as the campaign becomes more successful, the public will be completely impressed with the fact that the disease can be conquered. At that time, it may be expected that the true extent of the mortality from syphilis will be reflected by official statistics. Undoubtedly, most persons in this country prefer to face the facts openly and squarely, and will not intentionally withhold significant information once they are made cognizant of its value and importance.

SUMMARY

1. A confidential method of reporting causes of death, for deaths due to natural causes, has been used in the borough of Manhattan since

*The importance of the above cannot be over-emphasized. In New York City, for example, more than one-half of the deaths are certified from institutions where more than one practitioner is in attendance. Frequently, these institutions find it necessary to execute a death certificate at a time when no physician who attended the patient is available. Even when one of the physicians is available, it is not possible for him to be able to fill out the death certificate without reference to the case history.

The situation is quite similar for an additional one-fifth of the deaths in New York City, which are certified by the medical examiner's office. In addition to the information obtained from the hospital or private physician, the completed history for these cases may contain extensive notes resulting from the examiner's investigation. All of this information must be carefully considered both from the medical examiner's and the vital statistician's point of view when the death certificate is prepared.

January 1, 1939, and in all five boroughs of New York City since January 1, 1947.

2. In 1943-1944, a study was made of 5,652 deaths which were certified from proprietary hospitals in 1937-1939 and 1941, and of 1,678 deaths which were certified from selected municipal hospitals in January and February of those years.

3. Judged by diagnoses abstracted from hospital case histories, five conditions were found to be understated on death certificates. The official statistics for these 7,330 persons accounted for only 50 per cent of the mortality from alcoholism, 55 per cent for syphilis, 74 per cent for puerperal infection, 86 per cent for diabetes, and 87 per cent for appendicitis. Tuberculosis and cancer were found not to be understated.

4. There are no indications from the data that better statistics have resulted from the use of the confidential death certificate.

5. The trends in the recorded mortality in Manhattan, while the confidential report was used, closely paralleled those for the boroughs which used the open certificate. Comparative mortality data for the first 11 months of 1946 and 1947 also reveal no changes which might be attributed to the use of the confidential report in all boroughs of the city since January 1, 1947.

NOTE: Special acknowledgment is made to Kurt Pohlen, Ph.D., employed under a grant from the New York Foundation, for his technical assistance, especially for his painstaking and diligent efforts in abstracting the diagnoses and related information from the original hospital records.

Acknowledgment is also made to Drs. Allan Hurst, Alfred Koerner, and Oma H. Price of the Department of Health, and to the hospital superintendents, proprietors, record librarians, and many other persons whose assistance and coöperation helped to make the study possible.

The author is grateful for helpful suggestions in the preparation of this paper to Dr. Louis I. Dublin, Second Vice-President and Statistician, and Herbert H. Marks, Manager, Insurance Medical Statistics, both of the Metropolitan Life Insurance Company, and to many of the persons already mentioned.

The opinions expressed herein are those of the author and do not necessarily reflect the views of the New York City Department of Health, the members of the Statistical Advisory Committee, nor of the other persons to whom acknowledgment has been made.

Selecting Public Health Personnel Through Examining Processes

Gleanings from the Conference of Health Officers and
Merit System Supervisors *

DOROTHY DEMING, R.N., F.A.P.H.A.

Merit System Service, American Public Health Association, New York, N. Y.

THIS conference, which consisted of an interchange of experiences in the use of various examining processes for the selection of public health personnel, was attended by health department and merit system representatives. Discussion, led by Dan S. Moore, State Director of Personnel, Louisiana Civil Service Commission, was informal, and focused for the most part on the three currently employed methods of selecting personnel under merit system regulations: the rating of training and experience, the written test, and the oral interview, with brief consideration of the weights given each in relation to the level of position under scrutiny.

While there were no formal recommendations arrived at during this conference—such was not its purpose—some of the comments and conclusions of the group are of such timely interest to administrators as to warrant recording.

THE ORAL INTERVIEW

There are two major purposes for which oral interviews are used: to sample the candidate's knowledge of the field, and to evaluate such factors as his personality, appearance, and ability to think and speak logically and clearly. It was suggested that a written examination properly constructed to test a can-

didate's knowledge, yields a far more precise measure than does the oral interview. The group agreed, however, that an oral interview to evaluate appearance and personality is especially important in selecting public health personnel because so many of the staff must meet and deal daily with the public. No administrator present was willing to appoint a public health physician, nurse, or engineer without a personal interview, and a board of oral interview serves as a preliminary screening of candidates for such interviews.

The objections to oral tests that were mentioned included: (1) a misconception, occasionally held by candidates, to the effect that interviews are "fixed" in advance; (2) the difficulty in scoring objectively and weighting appropriately the factors to be measured by the interview; (3) the frequent lack of a verbatim record of the interview which makes it difficult to prove the basis on which the individual interviewers made their judgments. Even with these drawbacks, however, the majority seemed to feel that the oral interview is a very necessary step in selection, and eliminates those obviously unsuited from a personality standpoint. No one would give it up.

THE RATING OF TRAINING AND EXPERIENCE

While no one present could offer a truly valid and workable method of eval-

* Presented at the Seventy-fifth Annual Meeting of the American Public Health Association in Atlantic City, N. J., October 6, 1947.

uating experience and training of professional public health personnel, all agreed that such rating is very essential. It was pointed out that its value, and therefore the weight assigned to this rating, increases with the importance of the position. For example: a public health nursing supervisor's training and experience bear a more direct relation to her potential ability to do the job well than the training and experience of a graduate nurse who will serve as an assistant to a public health nurse in a clinic. In fact, several health officers present thought that the rating of training and experience, plus the oral interview were the only tools needed or wanted in their states in selecting public health physicians.

THE WRITTEN EXAMINATION

The group devoted considerable time to discussing the pros and cons of requiring written examinations of professional personnel.

Those in favor of making the written examination an intrinsic part of the selective procedure offered in support of their opinion their belief that the written test presents:

1. Clearcut, indisputable evidence with regard to a candidate's knowledge of facts, and, if the right type of questions are used, provides an excellent measure of his capacity for exercising sound judgment.

2. The most reliable means we have to date for *ranking* candidates objectively. Several merit system supervisors and health officers remarked on the success with which the examinations prepared by the Merit System Service differentiated between the well prepared and less well prepared candidates in their states.

Many of those present indicated that they would like to use the objective type of written tests for all positions, but stressed their inability to persuade some of the professional groups to take examinations, because these groups:

1. Resent taking still another examination when they are already graduates of medical and nursing schools and licensed to practise.

2. Dislike—and this is easily understandable—finding that in spite of years of experience, they occasionally make scores lower than candidates with far less experience.

3. Feel that an objective test measures theoretical knowledge only.

It was also pointed out that one very bad factor in requiring a written test is the hardship worked on the candidate who is ill on the day of examination and who must then wait until another examination is held before being placed on the register.

A few persons present went so far as to say that professional people who have passed licensing examinations should be exempt from written tests and be judged on a rating of their training and experience, and by an oral interview. Merit system supervisors immediately pointed out that while this procedure may work when only 3 or 4 candidates are applying, a finer, more objective screening must be devised when 30 or 40 candidates are being ranked. With the best of efforts, the rating of training which has taken place in 30 or 40 different institutions all using different grading methods is difficult, while an evaluation of experiences which have occurred under as many as 100 employers each of whom offers a subjective opinion of the candidate's performance, leaves the scorer hopelessly at sea.

All were agreed, however, that reluctance to take written tests will probably be overcome when the candidates find the examinations are professionally acceptable and appropriate to the level of duties of the job. Such an examination can be compiled only if the specifications are good—that is, give complete descriptions of the requirements for, and of, the job. There is much room for improvement in many of the present job specifications.

WEIGHTING THE SELECTIVE PROCESSES

The discussion then turned to weighting the three selective processes: the oral interview, rating of training and expe-

Beginnings of a Mental Health Program in a State and Local Department of Health*

KENT A. ZIMMERMAN, M.D.

Consultant for Mental Health, State Department of Public Health, San Francisco, Calif.

HEALTH officers in general recognize that a pressing need in their communities is the rapid development and expansion of mental health programs. Most feel that the community pressure is for the development of treatment clinics, and many people in health departments assume that that is the only kind of a program they can justifiably sponsor. Child guidance clinics and psychiatric clinics would probably be established by the thousands, almost overnight, if it were not for two very frustrating considerations, the lack of funds to operate a clinic and, even more serious, the inadequacy of well trained personnel. Many individuals, therefore, feel bewildered, and some discouraged when they find themselves blocked by these frustrations. In general, few people seem to see the work that is being done daily in the well baby, prenatal, tuberculosis, and venereal disease clinics, and in home visiting and family health counseling as being a very important opportunity for the promotion of mental health.

The reasons for such an attitude are perfectly justifiable. The usual well trained physician and nurse today do not think of themselves as capable of handling even simple emotional prob-

lems. Their professional education often did not give them this concept, and psychiatry itself has until very recently remained isolated from the rest of medicine. Consequently the general attitude in the majority of medical and nursing schools which seemed to be conveyed to the students, was that when there were problems of medical practice which related to feelings and attitudes, it was important to be aware of these, but, if possible, they should be left alone. This is one important reason why most doctors and nurses feel insecure when confronted with the emotions that accompany illness and convalescence. In many professional individuals there is also a lack of awareness of the importance of the emotional relationships that exist between doctor and nurse and patient, and their influence on both doctor and patient in everyday medical practice.

A growing number of people interested in mental health problems are coming to feel that a practical approach to the problem of meeting the mental health needs of communities could be made through professional workers already giving service to the communities. One of the most important of these groups is that of the health workers, who in company with school teachers, social workers, probation officers, and physicians in private practice, are concerned with helping people handle their problems and educating them toward

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

the self-responsibility of keeping happy and well.

WHAT ARE THE PROBLEMS?

In coöperation with the Commonwealth Fund, the California State Department of Public Health undertook a project to ascertain what kind of program might be necessary to promote incorporation of mental health principles as part of public health practice. In late 1946, two physicians, with training in pediatrics and psychiatry and some experience in public health, joined the staff of the State Department of Public Health. These physicians were myself and Dr. Martha MacDonald. Dr. MacDonald worked with us for three months and then, unfortunately for us, resigned to do purely clinical psychiatric work. The first thing we did was to make a study of the State Department of Public Health and three local departments of health in the San Francisco Bay area. We needed to learn something about the following:

1. Attitudes of staffs about psychiatry and mental hygiene
2. How the staffs felt mental hygiene and psychiatry might help with their work
3. What did the staffs feel capable of doing
4. What did staff members lack which prevented them from becoming more effective in promoting the emotional well-being of their patients
5. How this could be supplied to them within the limitations of time for training and the tremendous work load which each department and staff member faced

A brief description of our findings and impressions pertinent to this discussion give some of the answers to the above questions. A large number of public health workers are eager for staff training in mental health concepts. However, any training program has to take into consideration the fact that because of the extremely heavy work load

and the shortage of personnel, administrators are reluctant to give long periods of time to such training. At the same time, administrators feel the desire of their staffs for training in this field. They are beginning to understand that a high turnover of personnel is often the result of the blocking of professional individuals in their growth by overwork and the lack of opportunity for instruction. Highly trained personnel for education of local staffs cannot in general be attracted to local staffs because of the low salary scales. Local departments of health, therefore, are turning more and more to state departments of health for consultation, planning and financing of training programs.

Concepts about the training of local personnel are limited. Many health officers and nursing supervisors feel that a course of lectures on mental hygiene will meet the needs, and their thinking about education often stops here. Too infrequently do they see that a program needs to be planned so as to follow up in local public health practice what was covered in the lectures. One reason for this is that they feel that they need the mental hygiene expert to perform this task and rarely think of using people in their own communities who could supply another viewpoint and the discipline of another training such as school teachers, probation officers, social workers, etc.

In the majority of local health departments, where there are often only one or two full-time physicians, the backbone of clinical service is the public health nursing staff. The physicians who usually attend the clinics come for, perhaps, one afternoon a week and perform their duties and leave the health department alone the rest of the time. In the main, the physician performs the mechanical part of medical practice and when there is an important and emotionally-laden decision about the course of activities of an individual and his fam-

ily in relation to illness, this task is usually given to the nurse to handle. Even with the patient who has no major problem at the moment, it is the nurse in the clinic who often takes the history, explains the doctor's orders, or sees the patient functioning as part of the family. It should be no surprise, therefore, that the nurse is avidly seeking for information and guidance on normal emotional growth of individuals and their families. The nurses are the ones who have to support the insecure mother of the new baby, help the adult with tuberculosis to accept sanatorium care, get the patient with venereal disease to see responsibility in coming for treatment, etc. Yet the nurse is all the more insecure because her professional training and background have often been of an authoritarian nature, and she finds that this approach to the emotional problems such as she handles is rarely successful. Furthermore, as is also the case with physicians, she has often had no training whatever in the science and art of interviewing which both professions find again and again in their practice is the very thing they need most.

Another striking thing about many health departments is their utter lack of awareness of what other community agencies in their community are doing. Again, the person who interrelated these activities in the community was generally the public health nurse who, in her health work with families, needed to work with the social worker and the school teacher and sometimes the probation officer. However, the problem was mainly that the health department was so overwhelmed with work, as are the other community agencies, that its staff could rarely lift its eyes beyond its own confines and see itself as an important element in a total community picture of community services. This increased, therefore, the frustration of many sincere and conscientious individ-

uals who felt discouraged that there was so little they could do in meeting the emotional needs of their patients and families. This seemed to be because they thought in terms mostly of their own services, and, because of their lack of knowledge of the total community facilities, failed often to see the real importance of their own contribution to the patient.

Practically all the physicians who worked in the clinics felt a need for more knowledge of the normal individual, especially as to his growth and development, his reactions to illness, and his role in the doctor-patient relationship. Many physicians thought that this would help them in their practice as well as in their dealings with people everywhere. But also, it must be confessed, many physicians saw no particular reason for this since they were functioning quite successfully in their practices; and many felt that most simple emotional problems should be referred immediately to the psychiatrist.

Nurses stated they wanted more instruction about the normal emotions in children and adults and instruction on the techniques of interviewing. Occasionally an intuitive individual recognized that her own emotions and attitudes seemed to interfere or help in the treatment of some of her patients and would ask if some teaching could not be offered on this subject.

In summary it might be said that health workers are:

1. Eager for what psychiatry can offer them.
2. Belittle the potentially important mental health role they could play; feel they need the expert before anything can be done.
3. Feel inadequate in knowledge about the normal emotional behavior of children and adults. This is practically like saying that they want more confidence in knowing what human behavior really is.
4. Need more understanding of the emotional structure of the doctor-patient and nurse-patient relationship.
5. Want some instruction in interviewing and counseling.

In this local health department I worked at first as pediatrician in a typical well baby clinic. Our plan was to have the nurses of the staff rotate through this clinic. In addition to observing, each nurse was to select two or three patients or families who represented a problem in management or were of especial interest to her. The nurse was to keep good notes on these patients, especially of the interviews. At the end of each clinic session these patients were discussed from the standpoint of emotional change in both patient and nurse, or what some psychiatrists and psychiatric social workers call "movement" in the emotional interrelationship as it developed and waned. The object here was to simulate an approach to the case work situation which the learning social worker goes through in her training. In this way it is felt that some attention can be given to the nurse and her feelings so that she begins to learn and accept certain approaches which she as a personality can use in dealing with patients which affect the patients either positively or negatively in relation to their medical care. This experience, going on concomitantly with the lecture material given during the weekly nurses' staff meetings, required the integration of much more of the material into the nurse's personality. Likewise it provided a method of controlled growth of the individual in understanding the emotions of others and also those of herself in relation to her patients. The practical difficulty with this scheme was that we could not reach all the nurses on the staff with such personalized teaching.

A new scheme is now being developed. The health officer and the supervisor of nurses arranged that I attend a special well baby clinic to which all the nurses could refer two or three families from her district. We could thus have at least two nurses attend with their families at each session, and in a matter

of two to three weeks each nurse on the staff would have the opportunity to talk about how she felt about her patients and how she thought her patients felt about her.

I visit also the tuberculosis, crippled children screening clinic, rheumatic fever, and venereal disease clinics. This is more a consultation service discussing with the physicians and nurses those patients who refuse treatment, refuse hospital or sanatorium care, who become hostile in attitude, and those whose anxieties produce further symptoms and the like. Our policy here is to support and guide the nurse and the physician so that they handle these patient problems themselves rather than label the patient uncoöperative or refer him to the law officer or psychiatrist, if any is available.

Under the leadership of the health officer and the director of maternal and child health of the Richmond Health Department, the pediatricians in practice who attend the well baby clinics for the health department are considering meeting for a weekly luncheon at which the progress of our program will be followed and some discussions will be held on the mental health implications of office practice.

Along with this demonstration in a local health department it is contemplated that in coöperation with the Child Development Center of the Children's Hospital of the East Bay, the State Department of Public Health should also set up an experimental experience to see whether we can in another way supply some of the needs that nurses and physicians in public health, and medicine in general, do not get in their professional training. One of the great lacks for all physicians and nurses in their training has been an opportunity to understand and be with the normal child and get acquainted with the fact that he has emotions of hostility and anger which he must learn to in-

Volunteer Participation in Community Health in Hawaii*

RAYMOND GEORGE NEBELUNG, DR.P.H.

*Executive Director, Public Health Committee
Chamber of Commerce, Honolulu, T. H.*

ANY health problem, no matter how complicated, can be handled effectively if it is broken down into its different aspects. These individual problems can then be dealt with independently; but an integrated overall plan is essential so that the various programs will strengthen each other and eventually lead to unified community action.

For the past two and one-half years we have been building an organization for this purpose in Honolulu. The program is still in its developmental stages but sufficient progress has been made to indicate that lay persons not only are interested but are eager to assume responsibility in health activities under professional direction. Volunteer workers are being utilized with good results. Our first step was to study and to evaluate existing health programs in terms of community needs. Then it was possible to work out policies and procedures on the basis of available data and the coöperative concern of community groups. The second step was to make the facts known and to keep them before the public through a sustained and constructive educational program that will bring about action in these matters. Both lay and professional groups have participated in all phases of the work. We are endeavoring to make community needs better understood; and to secure

services more broadly conceived, adequately financed and administered.

The most difficult part of the demonstration has been the educational phase because it requires a sustained effort in which both lay and professional persons must participate if public interest is to be maintained. Furthermore, it necessitates a high quality of leadership, individual initiative, and a lot of time on the part of both groups.

The instrument which we are using to advantage to achieve our objective is a health council. Current membership in this activity includes 56 organizations, of which 35 per cent are civic organizations, 25 per cent professional groups, 22 per cent voluntary agencies, and 18 per cent official health agencies. The governing board consists of the council chairman, vice chairman, secretary, the chairmen of the three standing committees, two members elected by the council, and the two delegates representing the Public Health Committee of the Chamber of Commerce of Honolulu. Council expenditures are borne by the latter organization as a part of its contribution in the interests of promoting better community health. The professional personnel of the Public Health Committee function as the technical staff for the council. Planning and co-ordination are brought about through the program, education, and legislative committees, headed by lay and professional volunteers. Committee members are selected by each chairman, giv-

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

The other phase of the project consisted of the preparation of a health exhibit which features fourteen photo murals mounted on a mechanical page turner. Hawaiian scenes form the background. The exhibit was prepared for display in the Scientific Exhibit Section of the 75th annual meeting of the American Public Health Association.

In the development of our program we have been motivated by the desire to obtain greater interest and more participation in community health work on the part of the general public. Satisfactory progress can be achieved only through dynamic leadership and the support and utilization of professional and lay volunteer personnel.

Cutter Recalls All Dextrose Solutions

Dr. R. K. Cutter, President of Cutter Laboratories, on May 6 telegraphed the following information for readers of the *Journal*:

"Contamination has been found in another and entirely different glucose solution, dextrose 10 per cent in Ringers. The company is coöperating with the Food and Drug Administration, and is requesting the assistance of health departments throughout the country, in immediately recalling from hospitals Cutter's entire line of dextrose and other solutions for mass intravenous injection. Company officials believe that discovery of this new contamination makes questionable the use of any product pro-

duced in their intravenous solutions department until this entire contamination difficulty is solved. The other products produced in this department are concentrated dextrose, distilled water, sodium citrate, normal saline solutions in 50 and 100 cc. bottles, as well as all flasks supplied by Cutter for community blood and plasma banks.

"The reason for this contamination is still unknown, and until they have the positive answer, Cutter feel that this is the only step that can be taken in the interest of public safety. In the meantime, arrangements are being made to supply hospitals with solutions of other manufacturers."

further observation and control are more certain. The school group, from 7 to 14 years of age inclusive, comprises 2,145,000 individuals, equally divided between the two sexes. As a group for investigation, it represents 21.4 per cent of the total Colombian population. Its distribution among the 14 departments of the Republic fluctuates between 22.1 per cent and 19.6 per cent according to information compiled by the Contraloría General de la República. From January, 1945, until July 31, 1947, there were examined a total of 140,163 school children throughout the 14 departments. The number of those children affected by simple goiter was 79,505 or an incidence of 56.5 per cent.*

The criteria for the diagnosis and classification of simple goiter in reference to form, size, and consistency, were established in a unified fashion from the initiation of the project. All examination of persons and the registration of the data were in charge of a special medical commission created for that purpose.

2. With the data obtained from the survey there was made a national map of the distribution of simple goiter by departments.

Mere observation of this map permits full appreciation of the high incidence of simple goiter (from 37 to 81 per cent) in the departments in the interior of the country. This is in marked contrast to the low incidence (less than 10 per cent) in the coastal areas along the Atlantic and Pacific.

The great difference between the two percentages is highly significant. It is apparently explained by the greater consumption of iodine by the inhabitants of the coastal regions. That iodine is obtained from the atmosphere itself and

from foods of marine origin (including sea salt).

3. Based on the available historical data and the partial results of the survey on the incidence and distribution of simple goiter in Colombia, two very important premises may be established:

First, in some localities, formerly similarly affected by goiter, this endemia has been gradually disappearing, apparently as a result of better nutrition and the hygienic water supply for drinking purposes established for its inhabitants.

Second, for the last thirty years the endemia of simple goiter has been invading areas formerly untouched by it, such as—the Departments of Caldas and Antioquia. This has been due to the fact that the regional consumption of salt from iodized sources, has gradually been almost completely replaced by the use of salt from the large mines near Bogotá. The salt from these mines is extremely low in iodine content but it is cheaper, since it is exploited on a large scale and it is easily distributed to various centers of consumption due to the development of means of transportation throughout the country.

4. a. Simple goiter and drinking water—

The popular belief predominates in Colombia that the drinking of "hard water" is the cause of simple goiter.

In conjunction with the census of simple goiter, an attempt has been made to establish an association or correlation between these two phenomena; 209 water samples having been taken from 293 places included in the census.

The conclusions have been the following:

First, in places with "soft water" (up to 75 p.p.m.) and "semi-hard water" (up to 150 p.p.m.) the incidence of simple goiter fluctuates between 7 and 90 per cent.

Second, in localities where there is "hard water" or "very hard water" (more than 150 p.p.m.) the incidence

* These data include all the sizes of goiter (+ to +++++). If there are excluded the cases of (+), considered as transitory or "physiological," the incidence is reduced from 56.5 per cent to 35 per cent.

of simple goiter is always high, i.e., more than 45 per cent.

b. Simple goiter and climate—

There exists no correlation between these two phenomena. Simple goiter is distributed in an equal manner between the various climatic areas. (Cold climate—more than 6,000 feet above the sea level in altitude; temperate—between 2,500 and 6,000 feet above the sea level; and hot climate—less than 2,500 feet.) There is, however, a higher frequency in climates where anquilostomiasis or hookworm predominates.

c. Simple goiter and cretinism—

In some regions of Colombia, where simple goiter endemia is of long duration, there may be noted defects in physical development (stature shorter than that of the average) and abnormalities in mental development on a scale varying from the mentally retarded and "slow" to the cretin and the idiot.

5. Prophylactic Measures—The historical antecedents of the simple goiter endemia in Colombia, the determining factors in its invasion and extension into some regions, the significant difference between the incidence of the endemia in the interior and the coastal regions of the country—all lead one to consider the relative scarcity of iodine as the principal etiological factor in the incidence of simple goiter in Colombia. This, of course, does not exclude the effects of other contributory elements.

On the basis of this etiological premise, the Department of Nutrition proceeded to search for an adequate manner of furnishing a supplementary source of iodine—as a prophylactic measure against simple goiter. It was proposed to incorporate this supplementary iodine into ordinary kitchen salt for use by the inhabitants of the interior of the country.

As the first step in this procedure, the average daily consumption of salt per

capita was determined. This is 15 gm. Then, the optimum iodine content of the salt was calculated to be 4 mg. per 100 gm.

Samples of the salt, with a natural iodine content, from the old mines were analyzed but though the original iodine content was acceptable, the production capacity for the desired consumption was inadequate.

Samples were also analyzed for iodine content of the marine salt and the salt from the mines near Bogotá. The iodine content was almost equal.

It was then planned to iodize and stabilize the marine salt, but the project was abandoned because of technical difficulties and administrative problems (collapse of the production of the mines, social problems with labor, cost of transportation, etc.).

6. Artificial iodization of salt—

It was finally decided to iodize artificially and stabilize the salt from the mines of Zipaquirá, Nemocón and Sesquilé, situated almost in the geographical center of Colombia.

The manufacture of salt in powdered form from these mines follows a process which consists essentially of the following: (1) extract the mineral from the mines, (2) dissolve it in sweet water, (3) let it be purified and concentrated in a solution called "salmuera" up to 28-30 per cent salt, (4) evaporate the salt solution in containers of iron at a temperature of 98-100° C., (5) separate into precipitated salt, (6) permit to dry and transport for wholesale distribution in burlap sacks (retail sales per pound in paper sacks or wrapped in vegetable leaves).

At the present time there is manufactured and consumed a quantity of 100,000 tons of land salt per annum, destined for human use and for that of animals.

The method of artificial iodization tried out and adopted consists in adding to the salt solution—before it is placed in the iron caldrons—the mixture of

iodine and chemical stabilizing substances. This method does not require special machinery, obtains a uniform distribution of iodine throughout the salt, and results in being both simple in procedure and economic in cost. The stability of the iodine in the iodized salt is checked by samples submitted to various temperature and humidity conditions in cold, temperate, and hot climates, and in containers of ordinary paper. The loss of iodine content fluctuates between 3 and 4.5 per cent of the original content, after from 8 to 14 months subsequent to the time of the manufacture of the salt.

There is already information to determine the most adequate composition of the iodine mixture necessary in order to obtain a stabilized artificially iodized salt which is both cheap and easy to prepare.

7. Financing—Once the experimental studies were terminated, the Nutrition Division of the S.C.I.S.P. submitted for the approval of the Minister of Health in June, 1947, a project designed for two specific purposes: first, the artificial iodization of the salt from all the mines, and second, simultaneously with the first objective, to provide for the creation and the maintenance of the National Nutrition Institute for the study of the food and nutritional problems in Colombia.

The project for the financing of the proposed program consists essentially in the following phases: (1) the increase by 1 cent (Colombian) of the selling price of iodized salt over that of the common salt (this increase produces approximately Ps. 2,000,000 each year), (2) from this annual income, to pay the iodization expenses and to assign the total funds in excess of that cost for the creation and maintenance of the aforementioned Institute.

The original project of the Division of Nutrition was approved by the Minister of Hygiene and presented by him

to the Consejo de Ministros (meeting of national cabinet members) which entity also gave its approval. At the present time the proposal is under discussion by the National Congress, which body must pass it as a Law of the Republic. In the event that the proposal becomes law, the Division of Nutrition will have achieved two fundamental objectives: the prevention of simple goiter and the financing of a vast plan for the benefit of Colombian Nutrition. All this is being accomplished without burdening the budget of the Minister of Health nor that of the Servicio Cooperativo Interamericano de Salud Pública and at the cost of only 12 cents (Colombian) per annum to each inhabitant of the interior areas of Colombia. This accomplishment will be doubtless one of the most effective contributions of the Servicio Cooperativo Interamericano de Salud Pública in Colombia.

NOTE: The work and projects on simple goiter have had the approval and the unqualified support of the Directors of the S.C.I.S.P. in Colombia and of the Ministers of Hygiene throughout the entire period of the campaign. The Banco de la República—the entity in charge of the income proceeding from the exploitation of the salt mines throughout Colombia, has given every facility for the experiments on artificial iodization of salt on an industrial scale. In these studies and experiments, Dr. D. M. Hegsted of the Nutrition Division of the Schools of Medicine and Public Health of Harvard University—Asesor Técnico of Nutrition under contract to the Ministry of Health, Dr. Jacinto Caycedo—Medical Director of the Simple Goiter Commission in Colombia, and Dr. Alfonso Parra—Chemist of the Nutrition Laboratory—have given valuable assistance.

SUMMARY

1. Simple goiter is an ancient and serious problem of pathology in Colombia.
2. Surveys carried out on 140,000 school children, from 7 to 14 years of age inclusive, show an incidence of 56.5 per cent, including all sizes of goiter (+ to +++++). If there are excluded those cases of (+) value, the incidence is reduced to 35 per cent.
3. The history of simple goiter in Colombia, the process of its propagation to certain re-

gions of the country previously immune, and the marked difference of the incidence of the endemia between the school children of the interior (more than 50 per cent) and those of the maritime or coastal regions (less than 10 per cent) lead to the conclusion that the relative scarcity of iodine is the principal etiological factor of simple goiter, without excluding other factors such as anquilostomiasis (hookworm) and the quality of the drinking water.

4. In those regions of the Country where simple goiter is of long duration as an endemia (more than 100 years) there are observed cases, in children and in adults, with chronic defects in physical development (stat-ure shorter than that of the average) and with evidences of mental retardment (mentally "dull" and cretins).

5. As a preventive measure against simple goiter in behalf of the entire population of Colombia there is proposed the artificial iodization of the salt from the land mines, in the proportion of 4 mg. of iodine per each 100 gm.

of salt. The average daily intake of salt per capita is 15 gm.

6. In order to finance the artificial iodization of the salt there is proposed an increase of one or two cents in the selling price per pound of salt. This increase will produce an annual fund of from 2 to 4 million pesos (approximately 1 to 2 million U. S. dollars).

7. From this annual income will be paid the iodization expenses and the remainder of the money will be destined to the creation and maintenance of the Instituto Nacional de Nutrición (National Nutrition Institute).

8. The project for the artificial iodization of salt and the creation and maintenance of the National Nutrition Institute is at the present time under discussion by the National Congress of Colombia and has already received the approval of the Special Commission of the Senate.

9. The approval and realization of this project will be one of the most efficacious contributions of the Servicio Cooperativo Interamericano de Salud Pública in the benefit of the Colombian people.

Budgets and Expenditures for Dentistry from Maternal and Child Health Funds*

A study of the dental programs of selected states, 1938-1946

JOHN T. FULTON, D.D.S.

Dental Services Adviser, U. S. Children's Bureau, Washington, D. C.

CONTINUOUS planning of programs is one of the essential elements of public administration. To plan effectively it is essential to review and appraise the nature and extent of past activities in a particular field. One of the continuing jobs of an administrator, therefore, is to "pull out the files" and to inform himself of the experience of others.

For the most part the development of dental programs in state health departments followed the passage of the Social Security Act in 1935 when grants in aid became available to the states to extend and improve health services to mothers and children. The Children's Bureau, in administering Title V, Part I, of the Social Security Act, makes grants-in-aid to states on the basis of an annual plan and budget which is submitted by each state for maternal and child health services. The Children's Bureau further requires that each state at the end of the fiscal year submit for audit a report of the expenditure of these funds.

An examination of these records for dental items helps us in appraising what has developed, and should establish

bench marks for the continued planning of public dental programs.

Such a study is now under way in the Children's Bureau, and this paper is in the nature of a preliminary report, covering the budgets and expenditures of eight selected states for a period of 9 fiscal years from 1938 through 1946. The material presented is limited to the items concerning dentistry which appeared in the budgets and audited expenditures of the states. Only those items were recorded that could be clearly identified as dental expenditures. Lump sum reporting of supplies, equipment, or educational materials may have included items for the dental programs, but it was not possible to extract such amounts. It should be pointed out also that the amounts reported to the Children's Bureau by the states cover only federal funds and the money used by the states for matching these funds. The reported amounts, therefore, do not necessarily represent the entire sum spent by the various states for dental services. It should be emphasized that findings in the study are preliminary and subject to review in the light of future analysis.

For purposes of administration, the Children's Bureau has established 8 regional offices. One state from each of these regional jurisdictions was selected for this preliminary report on the basis

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 3, 1947.

that the dental program of the state health department had been maintained continuously for the 9 years under study. No other criteria were applied in the selection of the states. Thus it cannot be assumed that these states constitute a representative example from a national or regional point of view. These findings are, however, descriptive of continuing programs in the states concerned.

While it is beyond the scope of this paper to discuss administrative or program content, it is interesting that 7 of the 8 states have always employed full-time dental directors. Four of the 7 have served for the entire 9 years. The 1 part-time director has also headed up his state's dental program since its inception. In 2 cases, the directorship has changed and in 1 of the states the dental program operated for 2 years without a dentist in charge.

It is interesting further that by 1942 all of these states had brought their dental personnel under state merit system classification plans.

Almost one and three-fourths million dollars were earmarked for dental programs by these state health departments, three-fourths of which were subsequently expended. The amounts budgeted range from \$68,000 to \$427,000 per state, with half the states budgeting in the neighborhood of \$150,000. The proportion of these budgets which was actually spent ranges from 55 to 93 per cent with half of the states well above 80 per cent and 1 other state closely approaching that figure.

The related weight of dental expenditures to the total sums spent for maternal and child health services varied from over 11 per cent in 1939 to 6.5 per cent in 1945, rising again to 10 per cent in 1946. In this computation the expenditures for this group of 8 states are combined for each of the study years. The percentage remains fairly constant for the first 3 years and then tends to decrease through 1945, but rises sharply

back to its former level in 1946. Trend for individual states was varied. In 1 of the states the trend was consistently downward through the entire 9 year period. In another of the states no trend was evident, while in the other 6 states there was a great amount of fluctuation during the 1940's. As the United States was engaged in war during 4 of these years, it is possible that these fluctuations were caused by man power shortages and scarcity of materials and supplies. At this point, however, such considerations are matters of conjecture. Detailed study of this trend was not possible with the present material and will be reserved for a later, more detailed analysis.

Concerning expenditures for dentistry in 1938 and 1946, the first and last years studied and also the proportion of the total maternal and child health expenditures used for dentistry in those years, our study shows that 6 of the 8 states increased the amount of their dental expenditures substantially. In the states where there was an increase in the amount of dental expenditures in 1946 as compared with 1938, the increase ranged from \$3,510 for state No. 2 to \$40,390 in state No. 1. In the case of state No. 7 the funds decreased by approximately \$5,000, and in state No. 8 the decrease amounted to nearly \$25,000.

A breakdown of the dental expenditures over the 9 year period according to object (salaries, travel, supplies, fees, training, and health education) shows that the bulk of the total dental expenditures was involved in salary items in all the states, with the exception of state No. 4, the overall proportion of the total for this item being 71 per cent. Items for travel demanded the next largest outlay (11.4), with fees (9.8), supplies (5.9), training (1.1), and health education (0.7 per cent).

The salary items cover a variety of personnel, in the main full-time em-

ployees. Part-time dentists on a salary basis were listed by 4 of the states, one of them as previously stated being a director of his state's dental program. A summary of the latest classification plans of the states illustrates the types of personnel which made up the bulk of these salary items. Although the titles vary somewhat in the different states, in general, the personnel fall into 6 classes:

- Director of Dental Health
- Senior Public Health Dentist
- Junior Public Health Dentist
- Senior Dental Hygienist
- Junior Dental Hygienist
- Clerks and Stenographers

Travel items were listed for all types of professional personnel and included out-of-state trips.

Supplies covered a wide range of equipment such as dental instruments, chairs, engines, cabinets, laboratory equipment and instruments, dental supplies, automobile and trailers, as well as general office materials.

As pointed out earlier, sometimes supplies were lumped together as one item in the reports of expenditures. It is possible, therefore, that the total given here may not represent the entire expenditures for such materials.

Fees included payments to practising dentists for correctional dentistry in clinics or private offices, and for inspection, diagnostic and preventive services.

It is interesting to note that state No. 4 reported a much higher total of expenditures for these fee items than for salaries. Expenditures for fees in this state made up 56 per cent of the

total dental expenditures. Fees represented 13 per cent and 9 per cent of total dental expenditures in 2 other states. In the remaining states the payment of fees to practising dentists for clinical service constituted a very small proportion of the dental expenditures in these state programs.

Training embraced both graduate education for full-time personnel and refresher courses for practising dentists. The former included stipends and tuition. The latter type of training included both lecturers and clinicians who visited local groups of dentists, and the sending of local dentists to dental schools for short refresher courses.

Health education items were expended for publications, printing of leaflets, exhibits, visual education materials and equipment, and for the organization and conduct of institutes for teachers and lay people. Here too, these materials may have been grouped in general supply item reports which would not show.

Material has been presented for 8 selected states on the budgets and expenditures of dental programs in state health departments. Recognizing the limitations created by the small number of the states included, and the incompleteness of some of the items, the study nevertheless illustrates a useful approach to the problem of studying growth and change in the size of dental programs. The procedure outlined also delineates the relative importance of different types of expenditures under dental programs.

condition of adults who had acquired fluorosis of the teeth during childhood.

The data in the tables which follow were collected in the City of Colorado Springs, Colo., during the past three years, and are intended in part to supply this important information.

The observations summarized in Table 1 are not from a selected group of people but were made from persons as they presented themselves from day to day. All are natives of continuous residence with continuous use of the city water supply which has fairly consistently maintained a level of 2.6 p.p.m. of fluoride, since the first determinations were made several years ago.

The purpose of this paper is to show the actual condition that exists in this community after about 70 years of use of this water supply.

This is set forth in Table 1.

In addition to showing the average decay experience rate (untreated and filled teeth) in the different age groups, the table shows that this rate for the entire group is 2.98 per person. It will be noted also that slightly more than one-third (35 per cent) of these persons had experienced no decay whatever. The average age of the group is about 25 years. The age groups 10-14 and 15-19 show the remarkably low decay experience rates of 1.09 and 1.51 respectively, the decayed areas being practically limited to the fissures and pits in the molar teeth. The low incidence of caries experience in fluorosed upper anterior teeth cited by Dean² is confirmed by the present study, in which it was found that of the 1,192 teeth showing caries experience only 45 were in the incisor and cuspid group.

From the above it is apparent that decay of the proximal surfaces of fluorosed incisors and cuspids is almost negligible. The "standardized rate" of tooth loss as it appears in Table 1, has been accepted as a measure of the prevailing tooth loss from all causes. Table

1 shows a slowly increasing average decay experience rate as the ages advance, for which no explanation is suggested, but it is important to note that at the highest average rate shown (the 40-44 year group) the rate is considerably less than the *tooth loss* rate in the "standardized rate" table. The significance of these rates of decay experience and tooth loss can be best comprehended by comparison with a non-fluoride community such as the City of Madison, Wis. * This comparison is shown in Table 2 which was compiled by Dr. John G. Frisch of Madison.

The observations summarized in Table 3 were made in Colorado Springs and Montrose, Colo.,³ the persons examined having acquired fluorosis of the teeth in other widely scattered communities and districts through the use of domestic waters containing fluoride. These districts were generally in the middle and southwestern states and in other parts of Colorado.

Tables 1 and 3 bear a close similarity. Perhaps the most important comment pertaining to Table 3 is that the inhibitory effect of fluorine, once acquired, is permanent and is not diminished by later migrations. It is not necessary that the use of fluorinated water be continued. It is indicated also that the average rates of decay experience and tooth loss shown in Colorado Springs are by no means peculiar to that city alone. Examinations made in other communities using fluorinated water supplies, in various parts of the country, have shown that the average decay rate remains consistently at about 3 and that about one-third of the native persons are caries-free.⁴

It seems, therefore, that a pattern has been established which indicates what may be expected in any community that uses a fluorinated water supply. Bearing

* Madison is one of the cities that have recently undertaken a project for fluorination of its water supply.

TABLE 3
(Observed in Colorado Springs and Montrose, Colo.)
Summary of observations on 218 migratory persons having dental fluorosis

| Age Groups | 10-14 | 15-19 | 20-24 | 25-29 | 30-34 | 35-39 | 40-44 | 45 and above |
|---|-------|-------|-------|-------|-------|-------|-------|--------------|
| Number of persons examined | 51 | 80 | 32 | 20 | 13 | 8 | 7 | 7 |
| Number of persons showing no dental caries experience | 25 | 35 | 8 | 5 | 3 | 1 | 0 | 1 |
| Number of teeth showing dental caries or fillings | 76 | 155 | 93 | 66 | 43 | 28 | 36 | 33 |
| Number of teeth lost because of dental caries * | 8 | 7 | 3 | 1 | 0 | .. | .. | .. |
| Number of teeth lost (all causes) | 8 | 7 | 3 | 8 | 0 | 4 | 4 | 4 |
| Number of decayed or filled teeth per person | 1.49 | 1.93 | 2.90 | 3.30 | 3.30 | 3.50 | 5.14 | 4.71 |

* In the older groups it is not possible to determine accurately whether teeth were lost by caries or by other causes.

| | | | |
|---|------|---|------|
| Total number of persons | 218 | Average decayed and filled teeth per person | 2.43 |
| Number of persons showing no decay experience | 78 | Total number of teeth lost (all causes) | 38 |
| Per cent of persons showing no decay experience | 35.7 | Total number of incisor and cuspid teeth showing decay experience | 16 |
| Total number of teeth showing decay experience | 530 | | |

Comparison of Tooth Loss in this Migratory Group with "Standardized Rate"

| | | | | | | | | |
|--|------|------|------|------|-----|-----|------|-----|
| "Standardized Rate" * tooth loss per person | .. | 1.2 | 2.3 | 3.8 | 5.3 | 7.9 | 10.2 | .. |
| Tooth loss (all causes) per person in this migratory group | 0.15 | 0.08 | 0.09 | 0.40 | 0.0 | 0.5 | 0.5 | 0.5 |

* From, Klein, H. *J.A.D.A.* 30:80-96 (Jan.), 1943 (table 4); data represent 45,500 white U. S. Adults, all socio-economic groups.

on the relation between the degree of fluorosis of the teeth and the caries experience rate, a significant observation made on the Colorado Springs group was that in 137 of the first 300 persons examined the degree of fluorosis was classified as "mild." Their average caries experience rate was 2.46 and 55 (40 per cent) of this group were caries-free.

It has not been maintained that any benefit will accrue to teeth formed prior to the use of fluorinated water, and yet it cannot be said that this will not be the case. Reliable evidence bearing upon this point would be difficult to obtain, but there is a feeling that such teeth may experience some benefit.

Primarily this is a long-range influence directed toward the reduction of tooth decay in children and at the same time endowing the teeth with a resistance against decay that extends, as the tables show, well into adult life.

The chief research project in dentistry has been and still is to determine the
